The R Software

Fundamentals of Programming and Statistical Analysis

Pierre Lafaye de Micheaux
Rémy Drouilhet
Benoit Liquet
To the open-source community

To all those who have contributed, are contributing and will contribute to the awakening of our consciousness

To our colleagues from Montpellier, Grenoble, Bordeaux and ISPED
Foreword

This book has been translated from french by Robin Ryder, who is assistant professor in the CEREMADE (Centre De Recherche en Mathématiques de la Décision) at Université Paris Dauphine (France). We are very pleased that he has agreed to make this translation.

This book is based on notes from a series of lectures given for a few years at the Institut Universitaire de Technologie Grenoble 2, in the Department of Statistics and Business Intelligence (STID, Statistique et informatique décisionnelle). It has therefore been “digested” first, in a very imperfect form, by the students of this department, whom we thank here. Had they not shown so much interest, this book would probably never have existed. We also thank our colleague and friend Michel Lejeune, who managed to talk us into writing a manuscript and submitting it to Springer. It is worth pointing out the role of chance, which made the paths of the three authors cross in the same place for a few years. The human and scientific experience of this encounter was very enriching, and each author provided complementary skills which made it possible to overcome the tremendous amount of work necessary for this book. Finally, we wish to warmly thank our colleague and friend Matthieu Dubois, researcher in experimental psychology and addicted to R and to Macintosh, who was the first to read the french version of the book in its almost finalized version and gave us many ideas for improvement.

The contents of this book were chosen and organized in the best possible way for them to be exhaustive but also easy to assimilate by the reader. This book can be used as support material for lectures on R at any level from beginner to advanced. We have paid particular attention to the form of the book, which we think should aid understanding. It can also be used as a support for self-teaching. Note that most of this book can be useful to users of any operating system. However, a few chapters are mostly meant for users of Microsoft Windows. We have also felt it useful to give, occasionally, complements aimed at users of Linux or Macintosh.
All chapters follow the same structure. A chapter begins with a small insert listing the prerequisites necessary for the chapter, and a short description of the contents. All theoretical notions are explained with numerous examples, and include breaks so that the reader can put into practice on a computer the recently introduced notions. Each chapter ends with an assessment section: memorandum of most important terms, followed by a section of theoretical exercises (to be done on paper), which can be used as questions for a test. A practical sheet is also given at the end of each chapter. It can be used to check that the practical aspects of the chapter have been taken in. Note that all exercises and practicals only require the contents of the previous chapters.

The structure of the book is sequential. After a short introduction, aimed at getting the reader interested, and a description of a few data sets which will be used throughout the book to illustrate how to use R, the first part of the book is dedicated to the fundamental concepts of R: data organization, import and export, various manipulations, documentation, plots, programming and maintenance. This part should help you “learn the ropes” of R.

The second part of the book is dedicated to using R in a few mathematical and statistical settings. You should read the first part before moving on to this part, although it can be understood by users who already have a few notions in R. It covers R instructions for some of the main statistics and mathematics courses up to third-year undergraduate (for example, it covers the baccalauréate in statistics and actuarial sciences curriculum at Université de Montréal, as well as the French IUT curriculum in Statistics and Business Intelligence): matrix operations, integration, optimization, descriptive statistics, simulations, confidence intervals and hypothesis testing, simple and multiple linear regression, analysis of variance.

Finally, note that each statistical chapter in the second part relies on one or several real data sets, kindly made available by ISPED (Institut de santé publique, d’épidémiologie et de développement in Bordeaux) and described at the beginning of the book. These make learning more concrete and more attractive. We take this opportunity to thank all the teaching staff at the ISPED Masters in Public Health. These data, as well as several functions developed specially for this book and which are described or used here, are available in an R package associated with this book, called TheRSoftware. We also thank Mohamed El Methni and Taghi Barumandzadeh for the material they gave us for the chapter on ANOVA, and Hubert Raymondaud for many comments he has made on our French version which allowed us to significantly improve several parts of this book.
Alternative order of reading

We have used the symbol † to make explicit more difficult or less fundamental sections, which you can skip at first read without prejudicing your understanding or mastering of R.

Note that this book was conceived for students from a mathematical or statistical background. However, students or scientists from a more “applied” background can also use it: for these readers, we propose a different order of reading, as follows; the difficult sections should also be omitted.

PART I: THE BASICS OF R

a) Basic concepts; data organization (chapter 1).
b) Import-export and data production (chapter 2).
c) Data manipulation (chapter 3).
d) R and its documentation (chapter 4).
e) Techniques for plots (chapter 5).
f) Maintaining sessions (chapter 7).

PART II: ELEMENTARY STATISTICS

a) Random variables, distributions and simulation (chapter 10).
b) Descriptive statistics (chapter 9).
c) Confidence intervals and hypothesis testing (chapter 11).
d) Simple and multiple linear regression (chapter 12).
e) Elementary analysis of variance (chapter 13).

PART III: ADVANCED CONCEPTS

a) Basic mathematics: matrix operations, integration, optimization (chapter 8).
b) Programming in R (chapter 6).
**Inserts**

We have tried to be careful with the presentation of the book (the form), to make the information (the content) more easy going. Inserts are located at strategic points in the book, to help bring out some of the important information and make notions easier to understand. These inserts are distinguished by icons in the margin.

- **Tip**
  - Additional information about the topic under study.

- **Warning**
  - Important point you should pay attention to.

- **Note**
  - Advice and practical tricks.

- **See also**
  - Refers to another chapter or a website.

- **Advanced users**
  - Advanced elements. You can omit these at first.

- **Linux**
  - Information for Linux users.

- **Mac**
  - Information for Macintosh users.
Solutions to exercises and practicals

Solutions to exercises and practicals are given on the book’s website (http://www.biostatisticien.eu/springeR).

Other projects, more ambitious than the practicals, will be made available on the same website.

Font conventions

• The letter $\text{R}$ refers to the $\text{R}$ software.
• We use italics for words borrowed from Latin or French.
• We use a fixed width font (Verbatim environment) for $\text{R}$ instructions.
• We use SMALL CAPS for data sets and sans serif for the name of the file including these data sets. This font will be used for all file names and folder names used in this book.

Chapter A
Introducing R

Prerequisites and goals of this chapter

- You may find it useful to read the chapter on installing R in the Appendix first.
- This chapter presents the origins, objectives and specificities of R.

SECTION A.1
Presentation of the software

A.1.1 Origins

R is a piece of statistical software created by Ross Ihaka & Robert Gentleman [21].
It is both a programming language and a work environment: commands are executed
thanks to instructions coded in a relatively simple language; results are displayed as
text; plots are visualized directly in their own window. It is a clone of the software
S-plus, which is based on the object-oriented programming language S, developed
by AT&T Bell Laboratories in 1988 [3]. This piece of software is used to manipulate
data, draw plots and perform statistical analyses of data.

A.1.2 Why use R?

First of all, R is free and open-source. It works under UNIX (and Linux), Win-
dows and Macintosh: it is cross-platform. It is being developed in the free software
movement by a large and growing community of eager volunteers. Anyone can contribute to and improve R by integrating more functionalities or analysis methods. It is thus a quickly and constantly evolving piece of software.

It is also a very powerful and complete tool, especially adapted for statistical methods. The learning curve is steeper than for other software on the market (such as SPSS or Minitab): R is not the kind of software you can use out of the box with a few clicks of the mouse on menus. However, this approach has two advantages:

- it is didactic, since you have to understand a statistical method before you can put it at use;
- R is very efficient once you master it: you will then be able to create your own tools, enabling you to operate very sophisticated data analyses.

Warning

R is harder to comprehend than other software on the market. You need to spend time learning the syntax and commands.

R is especially powerful for data manipulation, calculations and plots. Its features include:

- an integrated and very well conceived documentation system (in English);
- efficient procedures for data treatment and storage;
- a suite of operators for calculations on tables, especially matrices;
- a vast and coherent collection of statistical procedures for data analysis;
- advanced graphical capabilities;
- a simple and efficient programming language, including conditioning, loops, recursion and input-output possibilities.

Note

For the readers already used to SAS, SPSS or Stata, we advise to read the books [32] and [33], and also to consult the two following internet web sites:

- http://rforsasandspssusers.com/
- http://www.statmethods.net/

Note also that it is possible to call R functions directly from Matlab using the R.matlab package and from Excel using the RExcelInstaller package. Reading of [20] might be useful in this context. Finally, a similar tool for OpenOffice, called R00o, exists; see the internet website http://rcom.univie.ac.at.
Many classical and modern statistical techniques are implemented in R. The most common methods for statistical analysis, such as:

- descriptive statistics;
- hypothesis testing;
- analysis of variance;
- linear regression methods (simple and multiple);
- and so on

are directly included at the core of the system. It should be noted that most advanced statistical methods are also available through external packages. These are easy to install, directly from a menu. They are all grouped and can be browsed on the website of the Comprehensive R Archive Network (CRAN) (http://cran.r-project.org). This website also includes, for some large domains of interest, a commented list of packages associated with a theme (called Task View). This facilitates the search for a package on a specific statistical method. Furthermore, detailed documentation for each package is available on the CRAN.

It should also be noted that recent statistical methods are added on a regular basis by the Statistics community itself.

---

**SECTION A.3**

**R and plots**

One of the main strengths of R is its capacity (much greater than that of other software on the market) to combine a programming language with the ability to draw high-quality plots. Usual plots are easily drawn using predefined functions. These functions also include many parameters, for example to add titles, captions, colours... But it is also possible to create more sophisticated plots to represent complex data such as contour lines, volumes with a 3D effect, density curves, and many other things. It is also possible to add mathematical formulae. You can arrange or overlay several plots in the same window, and use many colour palettes.
You can get a demonstration of the graphical possibilities in R by typing in the following instructions:

demo(image)
demo(graphics)
demo(persp)
demo(plotmath)
demo(Hershey)
require(lattice) # Load the package, which you must have
# previously installed by using the menu
# Packages/Install packages.
demo(lattice)
demo(rgl) # Same remark as above.
demo(rgl) # You can interact by using your mouse.
demo(persp3d)

The next figures shows a few of these plots.

Fig. A.1: A few of the graphical possibilities offered by R.
The R Graphical User Interface (GUI)

The R Graphical User Interface (i.e. its set of menus) is very limited, and completely nonexistent on some operating systems, when compared to other standard software. This minimality can set back some new users. However, this drawback is limited since:

- it has the didactic advantage that it incites users to know well the statistical procedures they wish to use;
- there are additional tools which extend the GUI.

In the next section, we present the package Rcmdr, which can be installed from the menu Packages, and which allows standard graphical and statistical analyses with a more user-friendly interface, which includes drop-down menus. Furthermore, the R instructions for the analysis chosen from the RCommander menus are displayed in dedicated panel. This can be useful if you do not know (or remember) the R instruction for a specific task.

**Tip**

Note that after you have learnt R thoroughly, you will be able to develop yourself tools similar to Rcmdr, made for a final users who does not desire to learn R but only to use, in the most user-friendly way, a procedure created by you. To this end, you can use the package tcltk.

**Warning**

Note that by using RCommander, we are distancing ourselves from what makes the strength and flexibility of R. We therefore advise against using such a tool if you wish to become an advanced user.

### A.5.1 Using RCommander

In this section, we offer a brief introduction to the package Rcmdr. We then present some functionalities given by this interface for statistical manipulations. We conclude by explaining how to add functionalities to the RCommander interface.
A.5.1.1 Launching RCommander

Follow these steps to start RCommander:

- Double-click on the R icon on your Desktop.
- In the console, type `install.packages("Rcmdr")`. Choose a nearby mirror.
- In the console, type `require(Rcmdr)`. Answer Yes to all the questions you may be asked. The RCommander graphical interface then opens. Another option is to click on the menu Packages, then Load package..., then Rcmdr.
- In the Messages panel, you should see WARNING: the Windows version of R Commander works better under RGui with the Single Document Interface (SDI).
- To remedy this issue, close RCommander.
- In RGui, go to Edit, then Preferences. Check SDI then click on Save... and on Save. You can take this opportunity to customize R.
- Restart R, then RCommander by typing `require(Rcmdr)` in the R console.

See also

We refer the reader to section C.2 which details how to install the package Rcmdr.

Mac

Macintosh users may find useful the instructions at http://socserv.mcmaster.ca/jfox/Misc/Rcmdr/installation-notes.html, after installing package tcltk which is available on the CRAN.

The graphical interface of RCommander includes four parts as shown on figure A.5.1.1:

A. Drop-down menus to perform specific tasks.
B. A Script window which presents the code executed thanks to click on a drop-down menu.
C. An Output window which gives the output of the executed code.
D. A Messages window giving a message on the last task.
A.5.1.2 Handling data with RCommander

To perform statistical analyses, you need data.

- **Entering data by hand**

  Follow these steps to enter data by hand.

  ▶ In the menu Data, choose New data set....
In the window **New data table**, choose a name for your dataset, for example Data1.

A data editor appears. Click on *var1* and replace it with *Name*. Enter a few names for this variable: Peter, Jack, Ben (see figure A.5.1.2).

Create a variable *Height* of type *numeric* with the following values: 182, 184, 190.

Click on the cross (X) at the top right corner of the active window to close the data editor.

You can visualize your dataset by clicking on *View*.

We can now calculate some basic statistics.

![Fig. A.3: Entering data with the RCommander graphical interface.](image)
Basic statistics.

Follow these steps to get some basic statistics on your data set:

- In the menu Statistics, choose Summary, then Descriptive statistics....
- A window called General statistics opens up; the only numeric variable in our data set is the variable Height.
- Choose the statistics Mean, Standard deviation and Quantiles, and click on OK.
- The result is displayed in the Output window. Note that you can check the R instruction which was used for this task in the Script window (see figure A.5.1.2).

Note that it is also possible to type an instruction directly in the Script window without using a menu. Here is an example.

- Type in the Script window:

```r
numSummary(Data1[, "Height"], statistics = c("mean", "sd"))
```

- Click on that line so that the cursor is displayed there, then click on Submit.
- You have just computed the mean and standard deviation of variable Height which contains 3 observations. The result appears in the Output window:

```
    mean     sd    %    n
 184.0000 5.291503 0 3
```
Manipulating the dataset.

In our toy example, suppose that we also have the weight and wish to compute the body mass index: \( BMI = \frac{\text{Weight}}{\text{Height}^2} \) (height in metres).

- Click on Edit (below the RCommander menus).
- The data editor opens up and you can add the numeric variable Weight, with the following values: 70, 72 and 75. Now close the data editor.
- In the Data menu, choose Manage variables in the active dataset, then Calculate a new variable.... A window opens.
- For Name of new variable, type BMI and for Expression to calculate: \( \text{Weight}/(\text{Height}/100)^2 \) (see figure A.5.1.2). Click on OK to complete the calculation.
- Click on View to see the result for your dataset.

You are starting to feel tired and need a coffee break! But before you take one, follow these steps to save your dataset.
A.5 First steps in R

Fig. A.5: Manipulating a dataset with RCommander.

- In the Data menu, choose Active dataset, then Save active dataset....
- A window opens. You can choose a location to save your dataset. We shall call it BMI and by default it has the .Rdata extension.
- Close RCommander and answer OK to the question Do you wish to quit? No to Save script file? and No to Save output file?.
- You can now close R and answer No to the question Save session image?.

▶ library(abind, pos=4)
▶ library(e1071, pos=4)
▶ numSummary(Datal, "Height", statistics=c("mean", "sd", "quantiles"), + quantiles=c(0.25, 0.5, 0.75, 1))
  mean   sd 0.25 0.50 0.75 1.00
  1.6 1.291803 1.80 1.81 1.82 1.86 1.90 3
▶ fix(Datal)
▶ library(relimp, pos=4)
▶ showData(Datal, placement="-20+200", font=3, maxwidth=100, maxheight=50)
After a well-deserved break, you wish to add new data to your file BMI.RData.

- Open an R session. Type `library(Rcmdr)`.
- In the Data menu, choose Load data set....
- A window opens. Navigate to and open the file BMI.RData.
- Click on View to display your dataset.
- Add the information for a new person ("Julia", Height=150, Weight=52) by clicking on Edit.
- After closing the editor, you can check the changes by clicking on View. You then see the value NA (Not Available) for Julia’s BMI.
- To get Julia’s BMI, you need to go through the steps of section Manipulating the dataset again. We shall see later on how to create a function which calculates the BMI in a more user-friendly fashion.

You now wish to send your dataset to a colleague who does not use R yet.

- In the Data menu, choose Active dataset, then Export active data set....
- A first window opens. Uncheck the box Write names of individuals (rows) since we have not defined these. Choose Spaces for the field separator.
- Click on OK. A second window opens. You can choose a place to save your dataset. We shall call it BMI and it has the default extension .txt.
- You can now send your dataset BMI.txt to your colleague, and use this opportunity to mention the wonderfulness of R, which has a rather user-friendly interface for data manipulation.

A.5.1.3 A few statistical tasks with RCommander

In this section, we present a brief overview of how to use RCommander for statistical tasks. We start with a mean comparison test and a chi-2 test of independence. We then show how to use RCommander to visualize the standard distributions (binomial, Poisson, Normal, Gamma, etc.). We conclude with a linear model fit.

- Mean comparison test.

We propose to use data already available in R. Follow these steps to load a dataset.

- In the Data menu, choose Data in packages, then Read data from an attached package....
- A window opens. Double-click on datasets in the Package section, then on sleep in the right column.
- sleep appears in the box Enter a dataset name (see figure A.5.1.3).
- You can now click on Help on the selected dataset to have some information about it.
- Click on OK to close the previous window, then visualize the dataset by clicking on View.
These data are used to compare the effect on sleep of a soporific drug, compared to a control group. We shall first visualize the distribution of sleep gain in both groups, then do a mean comparison test to see whether there is any difference between the drug and the control.

![R Commander interface with code and output]

Fig. A.6: Mean comparison test with R Commander.
In the Graphs menu, choose Box plot....
A window opens. Click on Plot by group.... then on the variable group, then on OK twice.
You can now see two box plots representing the sleep time gain in both groups.
You can save this plot by clicking on File, then Save as. Several formats are possible.

You can also enhance this plot, for example by adding colours. In the script window, type:

```r
boxplot(extra~group, ylab="extra", xlab="group", data=sleep, 
col=c("red","blue"))
```
then click on Submit.

See also

Chapter 5 is dedicated to plots in R.

We now perform a mean comparison test.

In the Statistics menu, choose Means, then independent t-test....
Click on group in section Groups (one). You now see specified the difference 1-2 (group 1 versus group 2).
Click on OK to see the result in the Output window (see also figure A.5.1.3).

The p-value of this test (greater than 5 %) does not allow us to conclude that there is a significant difference between the sleep gains given by the drug and the control.

- Test on a double entry table.

In a therapeutic test, the underlying question is whether a treatment on HIV positive mothers has an effect on the HIV status of the child. If it does not, then the HIV status of the child is independent of the treatment taken by the mother. In this test, out of 391 children, 100 are HIV negative, 193 have mothers under treatment, and 41 are HIV positive and have mothers under treatment. To know whether the treatment has an effect, follow these steps:

In the Statistics menu, choose Contingency tables, then Fill and analyse a double entry table....
A window opens. Fill the table as indicated in figure A.5.1.3. Choose Total percentages and Print expected frequencies.
Click on OK to see the result in the Output window.

At the 5 % risk level, we cannot conclude that the treatment has an effect on the child’s HIV status.
• Exploring distributions.

R Commander can be used to visualize standard distributions.

▶ In the Distributions menu, choose Continuous distributions, the Normal distribution, then Plot of normal distribution....
▶ A window opens. Specify a mean of 4 and a standard deviation of 2. Click on OK.
▶ The curve of the density of a normal distribution centred at 4 and with standard deviation 2 appears in a graphical window.

You can follow the same steps for other probability distributions.

• Fitting a linear model.

R Commander can be used to easily fit standard regression models. We illustrate this with the linear model. We shall first download a dataset from an Internet address (URL). It contains the measures, for 80 patients with a disabling illness, of
the variables GENDER (1=Male, 2=Female), WEIGHT (in kg), HEIGHT (in cm), PAIN (ordinal variable: a=least pain), DISTANCE (number of metres walked), MOBILITY (self-evaluation of mobility; 1=most mobile), STAIRS (number of steps climbed).

▶ In the Data menu, choose Import data, then from a text file, the clipboard or a URL....
▶ A window opens. Call the data table Illness. Check the box Internet link (URL) in Data file, and the box Tabulations for Field separator; Click on OK.
▶ In the field Internet Link (URL), type: http://biostatisticien.eu/springeR/illness.txt.
▶ Click on OK and you should see the following in the Messages window: The illness dataset contains 80 rows and 8 columns

We shall fit a multiple regression model. Follow these steps:

▶ In the Statistics menu, choose Model fitting, then Linear regression....
▶ Choose for example Model.1 as your model name in the field Enter a name for the model.
▶ Choose variable DISTANCE as the response variable, and variables WEIGHT and HEIGHT as the explanatory variables (keep the CTRL key pressed).
▶ Click on OK. The result of your linear model adjustment appears in the Output window. This result corresponds to the instructions:

\[
\text{Model.1} \leftarrow \text{lm(DISTANCE} \sim \text{WEIGHT+HEIGHT, data=Illness)}
\]

\[
\text{summary(Model.1)}
\]

which are shown in the Script window.

See also

Chapter 12 presents the linear model in further detail.

We now visualize the least squares plane corresponding to the fitted model.

▶ In the Plot menu, choose 3D plot, then 3D scatterplot....
▶ Choose variable DISTANCE as the response variable and the variables WEIGHT and HEIGHT as explanatory variables (use the CTRL key).
▶ Choose Ordinary least squares as the surface to fit. Click on OK.

You can now see the 3D scatterplot (shown in figure A.5.1.3), and the least squares plane. You can move the image with your mouse.
A.5.1.4 Adding functionalities to the RCommander interface

Some packages available on the official R website can also be integrated to the RCommander menus. They are easy to identify: their names start with RcmdrPlugin. We now illustrate how to use such a package.

See also

You can read the article [17] which explains how to build a package for RCommander integration.
**The TeachingDemos package.**

The RcmdrPlugin.TeachingDemos package can be used to illustrate some statistical concepts.

- Type `install.packages("RcmdrPlugin.TeachingDemos")` in the Script window. Click on Submit and choose a nearby mirror. Once the installation is complete, close and reopen RCommander using the instruction `Commander()`.  
- In the Tools menu, choose Load Rcmdr plug-ins..., click on OK and answer Yes to the question Restart now?.  
- There is a new menu called Demos. In this menu, you can choose for example the submenu Simple Correlation and explore the notion of correlation.

This plug-in also adds submenus to pre-existing menus. For example, in the Distributions menu, you can now choose Visualize distributions, then t distributions. By checking Show Normal Distribution, and by playing with the d.f. (degree of freedom) cursor, you can visualize the closeness of the Student distribution and the normal distribution.

**The sos package.**

The RcmdrPlugin.sos package can be used to ease the search for help on a given concept or function. Follow the same steps as before to install this plug-in. A new submenu called Search R Help ... (sos) appears in the Help menu. Explore this new Rcommander functionality, for example by typing linear model.

See also

Chapter 4 describes how to search for information about R.

**A.5.2 Using R with the console**

In the previous subsection, we saw how to use R through menus. In fact, this way of proceeding is far from optimal, since it imposes many limitations on the possibilities offered by R. Many analyses, either deeper or more recent and innovative, are not available in the RCommander menus. It is thus very useful to escape from the “button clicking” approach and master the R programming language. You will then be able to perform simulations and to code repetitive tasks. We have already encountered a few R instructions when using RCommander, which is itself a tool written in the R language. We now propose a brief introduction to a few elements of the R syntax, first through an analysis of complex data arising from a functional Magnetic Resonance Imaging (MRI) experiment, then by letting the reader type a few R commands and think about the output.
A.5 First steps in R

A.5.2.1 The strength of R shown on an example

Some neuroscientists work on finding which part of the brain deals with visual information on colour. To this end, a visual stimulus, consisting in an alternance of coloured and non-coloured moving patterns, is shown to a subject. During this time, volumic images of the subject’s brain are acquired at time \( t = 1, \ldots, T \) with an MRI scanner. Each 3D image is in fact a large (Rubik’s!) cube made of many voxels, the 3D equivalents of 2D pixels. At time \( t = 1, \ldots, T \), each voxel contains an electromagnetic measurement value \( x(t) \). We can thus consider that in each voxel, we have observed a time series \( \{x(t); t = 1, \ldots, T\} \) representing electromagnetic variations. The acquired data (given in file Mond4D.nii) thus consist in a 4-dimensional array, the concatenation of several volumic brain images measured through time.

We used R to find, in each brain slice, which voxel had temporal variations most correlated with the stimulus signal. The code below can be downloaded from http://biostatisticien.eu/springeR/brain-code.R, and opened thanks to the submenu Open script... of the File menu in R. The key combination CTRL+R then executes one by one the instructions of this script. You can try to execute these instructions to visualize the results. This will help you familiarize yourself with some of the possibilities offered by R.

We first download the data files we need (the files Mondanat.img and Mondanat.hdr contain an anatomical image of the subject’s brain).

```r
> getfile <- function(fichier)
+  download.file(paste("http://biostatisticien.eu/springeR/",
+                     fichier,sep=""),paste(getwd(),"/",fichier,sep=""),mode="wb")
> getfile("Mond4D.nii")
> getfile("Mondanat.hdr")
> getfile("Mondanat.img")
```

We then install the package to read the data.

```r
> install.packages("AnalyzeFMRI") # Choose a mirror.
> # File names.
> file.func <- paste(getwd(),"/","Mond4D.nii",sep="")
> file.anat <- paste(getwd(),"/","Mondanat.img",sep="")
> # Brain slice number.
> slice <- 10
```

The next instructions read the data.

```r
> anat.slice <- f.read.nifti.slice(file.anat,slice,1)
> class(anat.slice)
[1] "matrix"
> dim(anat.slice)
[1] 128 128
> func.slice <- f.read.nifti.slice.at.all.timepoints(file.func,slice)
> class(func.slice)
[1] "array"
```
We now create the coding of the visual stimulus signal (1 = colour, 0 = no colour).

```r
> stimulus <- c(rep(c(1,1,1,1,1,0,0,0,0,0,0,0,0,0,0,0),8),1,1,1,1,1)
> plot(stimulus,type="l")
```

We compute correlations between the observed time series in each voxel and the stimulus series.

```r
> corMat <- matrix(NA,nrow=128,ncol=128)
> for (i in 1:128) {
+   for (j in 1:128) {
+     corMat[i,j] <- cor(func.slice[i,j,],stimulus)
+   }
+ }

We can now compute the coordinates of the voxel most strongly correlated with the stimulus:

```r
> which(abs(corMat)==max(abs(corMat),na.rm=TRUE),arr.ind=TRUE)
row col
[1,] 67 117
```

and the correlation value of this voxel:

```r
> corMat[67,117]
[1] -0.6675017
```

We can then plot the time series observed in this voxel.

```r
> plot(stimulus,type="l")
> plot(func.slice[67,117,],type="l",ylab="Intensity")
```
We are now able to identify on the anatomical image of the brain the most active voxel for the visual stimulus.

```r
> image(as.matrix(rev(as.data.frame(t(anat.slice)))),col=gray((0:32)/32))
> points(117/128,67/128,col="red",cex=2,pch=19)
```

Note that you can also visualize these data in 3D. The following instructions, taken from the help file for the function `contour3d()` from package `misc3d`, give an interactive 3D view of the brain.

```r
> install.packages("misc3d")
> require(misc3d)
> a <- f.read.analyze.volume(system.file("example.img", + package="AnalyzeFMRI"))
> a <- a[,1]
> contour3d(a,1:64,1:64,1.5*(1:21),lev=c(3000, 8000, 10000), + alpha=c(0.2,0.5,1),color=c("white","red","green"))
```
A.5.2.2 A brief introduction of R syntax through some instructions to type

- Basic operations.

We advise the reader to play with these commands and try to understand how they work.

```r
> 1*2*3*4
[1] 24
> factorial(4)
[1] 24
> cos(pi)
[1] -1
> x <- 1:10
> x
[1]  1  2  3  4  5  6  7  8  9 10
> exp(x)
> x^2
[1]  1  4  9 16 25 36 49 64 81 100
> chain <- "R is great!"
> chain
[1] "R is great!"
> nchar(chain)
[1] 11
```
A.5 First steps in R

```r
> ?nchar
> M <- matrix(x, ncol=5, nrow=2)
> M

[1,] 1 3 5 7 9
[2,] 2 4 6 8 10
> M[2,3]
[1] 6
> L <- list(matrix=M, vector=x, chain=chain)
> L[[3]]
[1] "R is great!"
> function <- mini.game()
> function()
> function()
+
```

The following commands perform matrix operations.

```r
> A <- matrix(runif(9), nrow=3)
> 1/A

[,1] [,2] [,3]
[1,] 2.270797 1.546875 1.422103

Chapter B
A few data sets and research questions

Goals of this chapter
This chapter presents a few data sets from epidemiological studies analysed by various teams at the Bordeaux School of Public Health (Institut de Santé Publique, d’Épidémiologie et de Développement – ISPED). Each data set comes with a short research question, which will help understand the context of the study. They will be used throughout this book to show how to use the functionalities of R for importing and manipulating data and performing appropriate statistical analyses. For each data set, we give a table with a description, the variables and the coding. The reader should refer to this chapter when the data sets are mentioned later in the book. A table at the end of the chapter indicates in which chapters each data set is used. All these data sets are available online on the website associated with the book: http://www.biostatisticien.eu/springeR

SECTION B.1

Body Mass Index (BMI) of children

Presentation:
A sample of 152 children (3 or 4 years old) in their first year of kindergarten in schools in Bordeaux (Gironde, South-West France) underwent a physical check-up in 1996–1997.
Variables and coding:

<table>
<thead>
<tr>

SECTION B.2

Weight at birth

Presentation:

This study focused on risks associated with low weight at birth; the data were collected at the Baystate medical centre, Massachusetts, in 1986. Physicians have been interested in low weight at birth for several years, because underweight babies have high rates of infant mortality and infant anomalies. The behaviour of the mother-to-be during pregnancy (diet, smoking habits...) can have a significant impact on the chances of having a full term pregnancy, and thus of giving birth to a child of normal weight. The data file includes information on 189 women (identification number: ID) who came to the centre for consultation. Weight at birth is categorized as low if the child weighs less than 2,500 g.

Variables and coding:

<table>
<thead>
<tr>

SECTION B.3

Intima-media thickness

Presentation:

Atherosclerosis is the main cause of death for men above 35 and women above 45 in most developed countries. It is a thickening and hardening of internal artery walls. One of its consequences is myocardial infarction. An artery wall is made of three layers; innermost to outermost, they are called intima, media and adventitia. Intima-media thickness is a marker of atherosclerosis. It was measured by ultrasonography on a sample of 110 subjects in 1999 in Bordeaux hospitals. Information on the main risk factors was also collected.

Variables and coding:

Study case of myocardial infarction

Presentation:

The study for which the following data were collected aimed at examining whether women who use or have used oral contraceptives are at a higher risk of myocardial infarction. The sample includes 149 women who had myocardial infarction (cases) and 300 women who did not (controls). The main exposure factor is usage of oral contraceptives; the data also include: age, weight, height, tobacco consumption, hypertension, family history of cardiovascular diseases.

Variables and coding:

Part I
The bases of R
Chapter 1
Basic concepts and data organisation

Goals of this chapter
This chapter introduces the basic concepts of the R software (calculator mode, assignment operator, variables, functions, arguments) and the various data types and structures which can be handled by R.

SECTION 1.1

Your first session

Launch R by double-clicking its icon on the Windows Desktop (or from the Start menu). At the end of the text displayed in the R Console, you can see the prompt symbol >, inviting you to type in your first instruction in the R language.

R version 2.14.1 (2011-12-22)
Copyright (C) 2011 The R Foundation for Statistical Computing
ISBN 3-900051-07-0

R is free software and comes with ABSOLUTELY NO WARRANTY.
You are welcome to redistribute it under certain conditions.
Type ‘license()’ or ‘licence()’ for distribution details.

R is a collaborative project with many contributors.
Type ‘contributors()’ for more information and
‘citation()’ on how to cite R or R packages in publications.

Type ‘demo()’ for some demos, ‘help()’ for on-line help, or
‘help.start()’ for an HTML browser interface to help.
Type ‘q()’ to quit R.

>
This symbol invites you to give an instruction. For example, type "R is my friend", then validate by hitting the ENTER key (or RETURN). You will then get:

```
> "R is my friend"
[1] "R is my friend"
```

As you can see, R is well behaved and kindly proceeds with your request. This will usually be the case — maybe R is trying to compensate for its lack of conviviality. We shall explain later on why R's reply starts with [1].

### 1.1.1 R is a calculator

Like many other similar languages, R can easily replace all the functionalities of a (very sophisticated!) calculator. One of its major strengths is that it also allows calculations on arrays. Here are a few very basic examples.

```
> 5*(-3.2)       # Careful: the decimal mark must be a point(.)
[1] -16
> 5*(-3,2)       # otherwise, the following error is generated:
Error: ',' unexpected in "5*(-3,"

> 5^2            # Same as 5**2.
[1] 25
> sin(2*pi/3)    # Natural logarithm of 1.
[1] 0.8660254
> sqrt(4)        # Square root of 4.
[1] 2
> log(1)         # Creates a collection of the first five integers.
[1] 2 3 4 5
```

```
> c(1,2,3,4,5)*2  # Calculates the first five even numbers.
[1] 2 4 6 8 10
```

**Tip**

Any R code after the symbol “#” is considered by R as a comment. In fact, R does not interpret it.

You can now exit the R software by typing the following instruction: q().

You are asked whether you wish to save an image of the session. If you answer yes, the commands you typed earlier will be accessible again next time you open R, by using the “up” and “down” keyboard arrows.
1.1.2 Displaying results and variable redirecting

As you have probably noticed, R responds to your requests by displaying the result obtained after evaluation. **This result is displayed, then lost.** At first, this might seem sensible, but for more advanced uses, it is useful to redirect the R output to your request, by storing it in a variable: this operation is called **assigning the result to a variable.** Thus, an assignment evaluates an expression but does not display the result, which is instead stored in an object. To display the result, all you need to do is type the name of that object, then hit **ENTER**.

To make an assignment, use the **assignment arrow** <-. To type the arrow <-, use the lesser-than symbol (<) followed by the minus symbol (-).

To create an object in R, the syntax is thus:

```
Name.of.the.object.to.create <- instructions
```

For example:

```
> x <- 1  # Assignment.
> x      # Display.
[1] 1
```

We say that the value of x is 1, or that we have assigned 1 to x, or that we have stored in x the value 1. Note that the assignment operation can also be used the other way around ->, as in

```
> 2 -> x
> x
[1] 2
```

**Warning**

The symbol = can also be used, but its use is less general and is therefore not advised. Indeed, mathematical equality is a symmetrical relation with a specific meaning, very different to assignment. Furthermore, there are cases where using the symbol = does not work at all.

**Tip**

Note that a pair of brackets allows you to assign a value to a variable and display the evaluation result at the same time:

```
> (x <- 2+3)
[1] 5
```

If a command is not complete at the end of a line, R will display a different prompt symbol, by default the plus sign (+), on the second line and on following
lines. \texttt{R} will continue to wait for instructions until the command is syntactically complete.

\begin{verbatim}
> 2*8*10+exp(1)
[1] 162.7183
> 2*8*
+ 10+exp(
+ 1)
[1] 162.7183
\end{verbatim}

\begin{shaded}
\textbf{Warning}

Here are the \textbf{rules for choosing a variable name} in \texttt{R}: a variable name can only include alphanumerical characters as well as the dot (.), variable names are \textit{case sensitive}, which means that \texttt{R} distinguishes upper and lower case; a variable name may not include white space or start with a digit, unless it is enclosed in quotation marks "".
\end{shaded}

\subsection*{1.1.3 Work strategy}

- Take the habit of storing your files in a folder reserved to this effect (you could call it \texttt{Rwork}). We also advise you to type all your \texttt{R} commands in a script window called \textit{script} or \textit{R editor}, accessible through the “File/New script” menu. Open a new script window, click on the “Windows/Side by side” menu, then copy the script below:

\begin{verbatim}
x <- 5*(-3.2)
5^2
sin(2*pi/3)
sqrt(4)
c(1,2,3,4,5)
z <- c(1,2,3,4,5)*2
\end{verbatim}

- You can then use the key combinations \texttt{CTRL+A} (\texttt{COMMAND+A} on a Mac) to select all the instructions, then \texttt{CTRL+R} (\texttt{COMMAND+ENTER} on a Mac) to paste and execute them in one step in the \texttt{R} console. You can also execute a single line of \texttt{R}

\texttt{Mac}

On a Mac, the menu is “File/New Document”, and it is not possible to lay the windows side by side.

At the end of your session, you can save this script in the folder \texttt{Rwork}, for example as \texttt{myscript.R}, and reopen it during a later session from the menu “File/Open a script” (or on a Mac “File/Open Document”).
instructions from the script by hitting CTRL+R when the blinking cursor is on the relevant line of the script window.

Fig. 1.1: The script window and the command console.

Note in Figure 1.1 the presence of the STOP button that lets you interrupt a calculation that would last too long.

You can also use the function `source()` from the R console to read and execute the content of your file. This helps prevent overloading the console, as we will see later. You may find it useful to proceed as follows:

a) clicking once in the R console window;
b) going to the menu “File/Change current directory” (“Misc/Change work directory” on a Mac);
c) exploring your file system and select the folder Rwork;
d) typing in the console `source("myscript.R")`. Note that for the above example, the use of this instruction will not produce any output. The following
Do it yourself will clarify this point.

**Do it yourself**

Begin to create a folder called `Rwork` in your home directory. Then, type in and save in an R script the preceding instructions. The file containing the R script will be called `myscript.R` and will be put in `Rwork`. Now close then reopen R. Next, type the following instructions in the R console:

```r
rm(list=ls()) # Delete all existing objects.
ls() # List existing objects.
source("myscript.R")
ls()
x
z
```

Note that the `source()` function has permitted to execute the preceding instructions. You may have noticed that the computations which have not been redirected into variables do not have been printed. So their result is lost. Change your script and add the following instructions at the end of it:

```r
print(2*3)
print(x)
```

Save it, then source it. What happened?

- Take the habit of using the online R help. The help is very complete and in English. You can reach it with the function `help()`. For example, type `help(source)` to get help about the function `source()`.

**See also**

All these notions will be examined in further detail in Chapters 4 and 7.

**Tip**

For readers using a Microsoft OS, we suggest using the code editor Tinn-R, available at http://www.sciviews.org/Tinn-R/. It offers a better interaction between a script’s code and its execution. It also provides syntactic colouring of the code.
1.1 Your first session

Under Linux, note that the editors JGR and Emacs/ESS are available.

See also

You can consult the list of R editors on the webpage: http://www.sciviews.org/_rgui/projects/Editors.html.

Do it yourself

The Body Mass Index (BMI) is used to determine a person’s corpulence. It is calculated using the formula:

\[
\text{BMI} = \frac{\text{Weight (kg)}}{\text{Height}^2 (\text{m})}
\]

Calculate your BMI. You simply need to type the following lines in your script window:

```r
# You can type 2 instructions
# on the same line thanks to the symbol ;
My.Weight <- 75 ; My.Height <- 1.90
My.BMI <- My.Weight/My.Height^2
My.BMI
```

Execute this script by using the work strategy mentioned earlier. You can then modify this script to calculate your own BMI.

We propose a function to visualize your corpulence type. Execute the following instructions:

```r
source("http://www.biostatisticien.eu/springeR/IMC.R", encoding="utf8")
display.BMI(My.BMI)
```

You will learn how to program this kind of result in later chapters.

1.1.4 Using functions

We have already encountered a few functions: `sin()`, `sqrt()`, `exp()` and `log()`. The base version of R includes many other functions, and thousands of others can
be added (by installing packages, or by creating them from scratch).

Note that a function in R is defined by its **name** and by the list of its **parameters**. Most functions output a **value**, which can be a number, a vector, a matrix...

**Using** a function (or **calling** or **executing** it) is done by typing its name followed, in brackets, by the list of (formal) arguments to be used. Arguments are separated by commas. Each argument can be followed by the sign `=` and the value to be given to the argument. This value of the formal argument will be called effective argument, call argument, or sometimes entry argument.

We will therefore use the instruction

```r
functionname(arg1=value1, arg2=value2, arg3=value3)
```

where `arg1`, `arg2`, ... are called the arguments of the function, whereas `value1` is the value given to the argument `arg1`, etc. Note that you do not necessarily need to indicate the names of the arguments, but only the values, as long as you follow their order.

For any R function, some arguments must be specified and others are optional (because a default value is already given in the code of the function).

---

**Warning**

Don’t forget the brackets when you call a function. A common mistake for beginners is forgetting the brackets:

```r
> factorial
function (x)
gamma(x + 1)
<environment: namespace:base>
> factorial(6)
[1] 720
```

The output to the first instruction gives the code (*i.e.* the receipt) of the function, whereas the second instruction executes that code. This is also true for functions which do not require an argument, as shown in the following example:

```r
> date()
> date
function ()
.Internal(date())
<environment: namespace:base>
```

Obviously, this is not the place to comment the code of these functions.

To better understand how to use arguments, take the example of the function `log(x, base=exp(1))`. It can take two arguments: `x` and `base`. 
The argument \( x \) must be specified: it is the number of which we wish to calculate the logarithm. The argument \( \text{base} \) is optional, since it is followed with the symbol = and the default value \( \exp(1) \).

\begin{itemize}
  \item Tip
    An argument which is not followed with the symbol = must be specified. A parameter is optional if it is followed with =.
  \item Note
    In the following code, R will calculate the natural logarithm of the number 1, since the base argument is not specified:
    \begin{verbatim}
    > log(1)
    [1] 0
    \end{verbatim}
  \item Note
    For some functions, no argument needs to be specified, for example \texttt{matrix} which we shall encounter later on.
  \item One last important note is that you can call a function by playing with the arguments in several different ways. This is an important feature of R which makes it easier to use, and you will find it useful to understand this principle. To calculate the natural logarithm of 3, any of the following expressions can be used.
    \begin{verbatim}
    log(3)
    log(x=3)
    log(x=3,base=exp(1))
    log(x=3,exp(1))
    log(base=exp(1),3)
    log(base=exp(1),x=3)
    \end{verbatim}
  \item Warning
    Note that calling
    \begin{verbatim}
    log(exp(1),3)
    \end{verbatim}
    will calculate the logarithm of \( \exp(1) \) in base 3.
  \end{itemize}

Finally, recall that we have been able to see the code for the function \texttt{factorial()}:
\begin{verbatim}
> factorial
function (x)
  \texttt{gamma(x + 1)}
\end{verbatim}

This function was defined by the R developers with the following instructions:
\begin{verbatim}
> factorial <- function(x) \texttt{gamma(x+1)}
\end{verbatim}
It is very easy to code a new function in R, by using the function `function()`. For example, here is how to code a function which takes two arguments \( n \) and \( p \) and calculates the binomial coefficient \( \binom{n}{p} = \frac{n!}{p!(n-p)!} \):

```r
> binomial <- function(n,p) factorial(n)/(factorial(p)*factorial(n-p))
```

You can then use this new function as any other R function:

```r
> binomial(4,3)
[1] 4
```

We shall study in much further detail how to create more elaborate functions in Section 3.8 and in Chapter 6.

Note

In fact, there already exists an R function to compute the Newton binomial coefficient. This is the function `choose()` that works more efficiently, especially for big numbers.

---

### SECTION 1.2 Data in R

R, like most computer languages, can handle classical data types. R is actually able to automatically recognize data types according to the format of the input. One of the main strengths of R is its ability to organize data in a structured way. This will turn out to be very useful for many statistical procedures we will study later on.

#### 1.2.1 Data nature (or type, or mode)

Data “types” can be handled using the functions `mode()` and `typeof()`, which only differ in very subtle ways which we shall ignore.

Note

The function `class()` is more general: it is used to handle both data type and structuring. We shall study it later on. For ease of understanding, we shall use the command `typeof()`.

The various types (or modes) of data are now presented:
1.2 Data in R

1.2.1 Numeric type (numeric)

There are two numeric types: integers (integer) and real numbers (double).

If you enter

```r
> a <- 1
> b <- 3.4
> c <- as.integer(a)
> typeof(c)
[1] "integer"
```

the variables a and b are of the type "double", and the variable c has the same value as a, except that it has been forced to be of the type "integer". This is useful because it takes up less memory space. Instructions starting with as. are very common in R to convert data into a different type. We will see in the subsection 1.2.2.1 how to check that an object’s type is numeric.

1.2.1.2 Complex type (complex)

A complex number is created thanks to the letter i. The functions Re() for real part, Im() for imaginary part, Mod() for modulus, and Arg() for argument, can be used.
Here are a few examples:

```r
> 1i
[1] 0+1i
> z <- 1+2i
> typeof(z)
[1] "complex"
> is.complex(z) # To know whether an object is of the complex type.
[1] TRUE
> Re(z)
[1] 1
> Im(z)
[1] 2
```
1.2 Data in R

> Mod(z)
[1] 2.236068
> Arg(z)
[1] 1.107149

1.2.1.3 Boolean or logical type (logical)

The type logical is the result of a logical operation. It can take the values TRUE or FALSE. Here are a few instructions to create logical values:

> b>a
[1] TRUE
> a==b
[1] FALSE
> is.numeric(a)
[1] TRUE
> is.integer(a)
[1] FALSE
> x <- TRUE
> is.logical(x)
[1] TRUE

Warning
TRUE and FALSE can also be entered in a more condensed form by typing T and F, respectively. But this should not be encouraged.

When needed, this data type is naturally converted to numeric without having to specify the conversion: TRUE is worth 1 and FALSE is worth 0. The following example illustrates this point:

> TRUE + T + FALSE*F + T*FALSE + F
[1] 2

1.2.1.4 Missing data (NA)

A missing or undefined value is indicated by the instruction NA (for non available). Several functions exist to handle this data type. In fact, R considers this data type as a constant logical value. Strictly speaking, it is therefore not a data type. Here are a few examples which use the instruction NA:

> x <- c(3,NA,6)
> is.na(x)
[1] FALSE TRUE FALSE
> mean(x) # Trying to calculate the mean of x.
[1] NA
> mean(x,na.rm=TRUE) # The na.rm argument means that NA’s should be ignored (NA.remove).
[1] 4.5
This is a very important notion when it comes to reading statistical data files. We shall examine it in further detail in Chapter 3.

**Warning**

Do not mistake `NA` for the reserved word `NaN`, which means *not a number*:

```r
> 0/0
[1] NaN
```

Note also that the following instruction does not output `NaN` but infinity, represented in R with the reserved word `Inf`.

```r
> 3/0
[1] Inf
```

### 1.2.1.5 Character string type (`character`)

Any information between quotation marks (single `'` or double `"` ) corresponds to a character string:

```r
> a <- "R is my friend"
> mode(a)
[1] "character"
> is.character(a)
[1] TRUE
```

Conversions into a character string from another type are possible. Converting a character string into another type is possible as long as R can correctly interpret the content inside the quotations marks. Note that some conversions are done automatically. Here are a few examples:

```r
> as.character(2.3) # Conversion into a character string.
[1] "2.3"
> b <- "2.3" # Conversion from a character string.
> as.numeric(b)
[1] 2.3
> as.integer("3.4") # Conversion from a character string.
[1] 3
> c(2,"3") # Automatic conversion.
[1] "2" "3"
> as.integer("3.four") # Impossible conversion.
[1] NA
```
1.2 Data in R

Note

The differences between single and double quotation marks are given in Chapter 3.

1.2.1.6† Raw data (raw)

In R, it is possible to work directly with bytes (displayed in hexadecimal format). This can sometimes be useful when reading certain files in binary format. We shall see examples in Chapter 5.

```r
> x <- as.raw(15)
> x
[1] 0f
> mode(x)
[1] "raw"
```

Summary

Table 1.1: The various data types in R.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Type in R</th>
<th>Display</th>
</tr>

<td>character</td>
<td>&quot;text&quot;</td>
</tr>
<tr>
<td>binary</td>
<td>raw</td>
<td>1c</td>
</tr>
</tbody>
</table>

Tip

The function `storage.mode()` get or set the type or storage mode of an object.

1.2.2 Data structures

In R, you can organize (structure) the various data types defined above. The structures we are about to present can be accessed or created with the function `class()`.
1.2.2.1 Vectors (vector)

This is the simplest data structure. It represents a sequence of data points of the same type. A vector can be created with the function `c()` (for collection or concatenation). Other functions such as `seq()` or a colon can also be used to create a vector. Note that when creating a vector, it is possible to mix data of different types. R will then make an implicit conversion into the more general data type, as shown in the following example:

```r
> c(3,1,7)
[1] 3 1 7
> c(3,TRUE,7)
[1] 3 1 7
> c(3,T,"7")
[1] "3" "TRUE" "7"
> seq(from=0,to=1,by=0.1)
[1] 0.0 0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9 1.0
> seq(from=0,to=20,length=5)
[1] 0 5 10 15 20
> vec <- 2:36
> vec
[1] 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20
```

Note that it is possible to “name” the elements of a vector using the function `names()`.

```r
> vec <- c(1, 3, 6, 2, 7, 4, 8, 1, 0)
> names(vec) <- letters[1:9] # 9 first letters of the alphabet.
> vec
 a b c d e f g h i
1 3 6 2 7 4 8 1 0
```

Warning

The indications [1] and [20] give the rank in the vector vec of the element they precede.

```r
> is.vector(vec)
[1] TRUE
> x <- 1:3
> x
[1] 1 2 3
> y <- c(1,2,3)
> y
[1] 1 2 3
> class(x)
[1] "integer"
> class(y)
[1] "numeric"
```
One would actually expect to see appear "vector of doubles" or "vector of integers" instead of "numeric" or "integer", but no software is perfect!

Note that the instructions `c()` and `:` give the same output, but that `x` and `y` are stored internally in different ways. The type `integer` uses less memory than the type `numeric`.

### 1.2.2.2 Matrices (matrix) and arrays (array)

These two notions are generalizations of the vector notion: they represent sequences with two indices for matrices, and with multiple indices for arrays. As with vectors, **elements must be of the same type**.

The following instruction

```r
> X <- matrix(1:12, nrow=4, ncol=3, byrow=TRUE)
> X
[,1] [,2] [,3]
[1,]  1  2  3
[2,]  4  5  6
[3,]  7  8  9
[4,] 10 11 12
```

creates (and stores in the variable `X`) a matrix with four rows and three columns, filled by row (byrow = TRUE) with the elements of the vector `1:12` (*i.e.* the twelve first integers).

Similarly, a matrix can be filled by column (byrow = FALSE).

```r
> Y <- matrix(1:12, nrow=4, ncol=3, byrow=FALSE)
> Y
[,1] [,2] [,3]
[1,]  1  5  9
[2,]  2  6 10
[3,]  3  7 11
[4,]  4  8 12
```

```r
> class(Y)
[1] "matrix"
```

The function `array()` is used to create multidimensional matrices with more than two dimensions, as shown in the following figure (for a three-dimensional array).
Basic concepts and data organisation

Fig. 1.3: Illustration of an array.

```r
> X <- array(1:12,dim=c(2,2,3))
> X
,,1 [,1] [,2]
[1,] 1  3
[2,] 2  4
,,2 [,1] [,2]
[1,] 5  7
[2,] 6  8
,,3 [,1] [,2]
[1,] 9 11
[2,] 10 12
> class(X)
[1] "array"
```

Arrays with more than three dimensions can be created thanks to the argument `dim`, which can be of length greater than 3.

1.2.2.3 Lists (`list`)

The most flexible and richest structure in R is the list. Unlike the previous structures, lists can group together in one structure data of different types without altering them. Generally speaking, each element of a list can thus be a vector, a matrix, an array or even a list. Here is a first example:

```r
> A <- list(TRUE,-1:3,matrix(1:4,nrow=2),c(1+2i,3),
+ "A character string")
```
1.2 Data in R

> A
> [[1]]
> [1] TRUE
> [[2]]
> [1] -1 0 1 2 3
> [[3]]
> [ ,1] [ ,2]
> [1,] 1 3
> [2,] 2 4
> [[4]]
> [1] 1+2i 3+0i
> [[5]]
> [1] "A character string"
> class(A)
> [1] "list"

In such a structure, with heterogeneous data types, element ordering is often completely arbitrary. Elements can therefore be explicitly named, which makes the output more user-friendly. Here is an example:

> B <- list(my.matrix=matrix(1:4,nrow=2),
+ my.complex.numbers=c(1+2i,3))
> B
$my.matrix
 [ ,1] [ ,2]
 [1,] 1 3
 [2,] 2 4
$my.complex.numbers
 [1] 1+2i 3+0i
> list1 <- list(my.complex.number=1+1i,my.logical.value=FALSE)
> list2 <- list(my.string="I am learning R",my.vector=1:2)
> C <- list("My first list"=list1,My.second.list=list2)
> C
$'My first list'
$'My first list'$my.complex.number
 [1] 1+1i
$'My first list'$my.logical.value
 [1] FALSE
$My.second.list
$My.second.list$my.string
 [1] "I am learning R"
$My.second.list$my.vector
 [1] 1 2

See also

Naming elements will make it easier to extract elements from a list (see Chapter 3, page 104).
1.2.2.4 The individual×variable table (data.frame)

The individual×variable table is the quintessential structure in Statistics. In \textit{R}, this notion is expressed by a data.frame. Conceptually speaking, it is a matrix with each line corresponding to an individual, and each column corresponding to a variable measured on the individuals. \textbf{Each column represents a single variable, which must be of the same type across all individuals.} The columns of the data-matrix can have names. Here is an example of a data.frame creation:

```r
> BMI <- data.frame(Gender=c("M","F","M","F","M","F"),
+                   Height=c(1.83,1.76,1.82,1.60,1.90,1.66),
+                   Weight=c(67,58,66,48,75,55),
+                   row.names=c("Jack","Julia","Henry","Emma","William","Elsa"))
```

```r
> BMI

<table>
<thead>
<tr>
<th></th>
<th>Gender</th>
<th>Height</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jack</td>
<td>M</td>
<td>1.83</td>
<td>67</td>
</tr>
<tr>
<td>Julia</td>
<td>F</td>
<td>1.76</td>
<td>58</td>
</tr>
<tr>
<td>Henry</td>
<td>M</td>
<td>1.82</td>
<td>66</td>
</tr>
<tr>
<td>Emma</td>
<td>F</td>
<td>1.60</td>
<td>48</td>
</tr>
<tr>
<td>William</td>
<td>M</td>
<td>1.90</td>
<td>75</td>
</tr>
<tr>
<td>Elsa</td>
<td>F</td>
<td>1.66</td>
<td>55</td>
</tr>
</tbody>
</table>
```

```r
> is.data.frame(BMI)
[1] TRUE

> class(BMI)
[1] "data.frame"

> str(BMI)
'data.frame': 6 obs. of 3 variables:
$ Gender: Factor w/ 2 levels "F","M": 2 1 2 1 2 1
$ Height: num 1.83 1.76 1.82 1.6 1.9 1.66
$ Weight: num 67 58 66 48 75 55
```

The \texttt{str()} function enables one to display the structure of each column of a data.frame.

\textbf{Advanced users}

A data.frame can be seen as a list of vectors of identical length. This is actually how \textit{R} stores a data.frame internally.

```r
> is.list(BMI)
[1] TRUE
```

1.2.2.5 Factors (factor) and ordinal variables (ordered)

In \textit{R}, character strings can be organized in a more astute way thanks to the function \texttt{factor()}:
> x <- factor(c("blue", "green", "blue", "red", + "blue", "green", "green"))
> x
[1] blue green blue red blue green green
Levels: blue green red
> levels(x)
[1] "blue"  "green"  "red"
> class(x)
[1] "factor"

The function `cut()` enables one to recode a continuous variable into a factor.

> Poids <- c(55, 63, 83, 75, 90, 73, 67, 84, 87, 79, 48, 52)
> cut(Poids, 3)
Levels: (48,62] (62,76] (76,90]

Factors can of course be used in a data frame. R indicates the different levels of the factor. The function `factor()` should thus be used to store qualitative variables. For ordinal variables, the function `ordered` is better suited:

> z <- ordered(c("Small", "Tall", "Average", "Tall", "Average", + "Small", "Small"), levels=c("Small", "Average", "Tall"))
> class(z)
[1] "ordered" "factor"

The `levels` argument of the function `ordered` is used to specify the order of the variable’s modalities.

Examples of uses of these two functions are given in Chapter 9, pages 339 and 341.

The function `gl()` generate factors by specifying the pattern of their levels.

> gl(n = 2, k = 8, labels = c("Control", "Treat"))
[1] Control Control Control Control Control Control Control
[8] Control Treat Treat Treat Treat Treat Treat Treat
[15] Treat Treat
Levels: Control Treat
In the above instruction, \( n \) and \( k \) are two integers, the first one giving the number of levels and the second one the number of replications.

Advanced users

A vector of character strings can be organized in a more efficient way by taking into account repeated elements. This approach allows better management of the memory: each element of the factor or of the ordinal variable is in fact coded as an integer.

### 1.2.2.6 Dates

\( \text{R} \) can be used to structure the data representing dates, using the `as.Date()` function for example.

```r
> dates <- c("92/27/02", "92/02/27", "92/01/14", "92/02/28", "92/02/01")
> dates <- as.Date(dates, "%y/%m/%d")
> dates
> class(dates)
[1] "Date"
```

We will return in detail on the functions for manipulating dates in Chapter 3.

### 1.2.2.7 Time series

When data values are indexed by time, it may be useful, using the `ts()`, to organize them into an \( \text{R} \) structure that reflects the temporal aspect of these data.

```r
> ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of # 1959.

             Qtr1 Qtr2 Qtr3 Qtr4
1959          1  2  3          # 1959.
1960          4  5  6  7
1961          8  9 10
```

The reader may consult with profit the book [40] which outlines the basic techniques for modeling time series, present the \( \text{R} \) functions to use for these models, and give applications of these functions on several real datasets.
## Summary

Table 1.2: The various data structures in R.

<table>
<thead>

Memorandum

-, ->: variable assignment arrows
mode(), typeof(): gives the nature of an object
is.numeric(): determine whether an object is numerical
TRUE, FALSE, is.logical(): True, False, determine whether an object is a boolean
is.character(): determine whether an object is a character string
NA, is.na(): Missing value, determine whether a value is missing
class(): determine the structure of an object
c(): create a sequence of elements of the same nature
matrix(), array(): create a matrix, a multidimensional table
list(): create a list (collection of different structures)
data.frame(): create an individual × variable table
factor(): create a factor

Exercises

1.1- What is the output of this instruction: 1:3^2?
1.2- What is the output of this instruction: (1:5)*2?
1.3- What is the output of these instructions: var<-3? Var*2?
1.4- What is the output of these instructions: x<-2? 2x<-2*x?
1.5- What is the output of these instructions: root.of.four <- sqrt(4)?
       root.of.four?
1.6- What is the output of these instructions: x<-1? x<- -1?
1.7- What is the output of this instruction: An even number <- 16?
1.8- What is the output of this instruction: "An even number" <- 16?
1.9- What is the output of this instruction: "2x" <- 14?
1.10- What is the output of this instruction: An even number?
1.11- Two symbols have been removed from this R output. What are they?
> 2
+ [1]  6
1.12- What is the output of this instruction: TRUE + T + FALSE*F + T*FALSE + F
      ?
1.13- Name the five data types in R.
1.14- Give the R instruction which gives the following output:
> x
   [,1] [,2] [,3]
[1,]  1  5  9
[2,]  2  6 10
[3,]  3  7 11
[4,]  4  8 12
1.15- Names the data structures (classes) available in R.

**Worksheet**

**Study of Body Mass Index**

We wish to analyse the characteristics of a sample of children. These children went through a medical examination in their first year of kindergarten in 1996-1997 in schools in Bordeaux (South-West France). The sample below contains information on ten children between the ages of 3 and 4.

The following information is available for each child:

- gender: G for girls and B for boys;
- whether their school is in a ZEP (*zone d’éducation prioritaire*: area targeted for special help in education, recognized as socially deprived): Y for yes and N for no;
- age in years and months (two variables: one for years and one for months);
- weight in kg, rounded to the nearest 100 g;
- height in cm, rounded to the nearest 0.5 cm.

In Statistics, it is of the utmost importance to know the type of the variables under study: qualitative, ordinal or qualitative. These types can be specified in R thanks to the structure functions we introduced earlier in this chapter.

Try the following manipulations under R. Remember to use the work strategy we presented at the beginning of the chapter.

1.1- Choose the best R function to save the data from each variable in vectors which you will call *Individuals, Weight, Height* and *Gender*.

1.2- Where possible, calculate the mean of the variables.

1.3- Calculate the BMI of the individuals. Group the results in a vector called *BMI* (be careful of the units).

1.4- Group these variables in the R structure which seems most appropriate.
1.5- Use R’s online help to get information on the `plot()` function.
1.6- Make a scatter plot of `Weight` as a function of `Height`. Remember to add a title to your graph and to label your axes.
Chapter 2
Importing, exporting and producing data

Prerequisites and goals of this chapter

- Chapter 1.
- This chapter describes the instructions to enter data in R. It presents the various possibilities R offers to import or export data, to and from software as different as Excel, SPSS, Minitab, SAS or Matlab. It also shows how to interact with databases (SQL queries). You may benefit from reading the (very complete) manual http://cran.r-project.org/doc/manuals/R-data.pdf.

SECTION 2.1

Importing data

2.1.1 Importing data from an ASCII text file

Either your data are already available in a text file in the ASCII format, or you can enter them by hand using a text editor such as Wordpad under Microsoft Windows, or Emacs under Linux.

Note

Entering data by hand can be done for a small number of values. If you are dealing with large amounts of data, it is more convenient to use a spreadsheet (see the next section).
The three main R functions to import data from a text file are presented in the following table.

<table>
<thead>
<tr>
<th>Function name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>read.table()</td>
<td>Best suited for data sets presented as tables, as it is often the case in Statistics.</td>
</tr>
<tr>
<td>read.ftable()</td>
<td>Reads contingency tables.</td>
</tr>
<tr>
<td>scan()</td>
<td>Much more flexible and powerful. Use this in all other cases.</td>
</tr>
</tbody>
</table>

### 2.1.1 Reading data with read.table()

The following R instruction will read the data present in a file (to be chosen in a dialog window) and import them into R as a data.frame which we have chosen to call `my.data`.

```r
my.data <- read.table(file=file.choose(), header=T, sep="\t", dec=".", row.names=1)
```

The function `read.table()` accepts many arguments; the most common are described in the following table.

<table>
<thead>
<tr>
<th>Argument name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file=</td>
<td>Location and name of the file to be read.</td>
</tr>
<tr>
<td>header=TRUE</td>
<td>Logical value indicating whether the variable names are given on the first line of the file.</td>
</tr>
<tr>
<td>sep=&quot;\t&quot;</td>
<td>The values on each line are separated by this character (&quot;\t&quot;=TABULATION; &quot;&quot;=whitespace; &quot;,&quot;=; etc.).</td>
</tr>
<tr>
<td>dec=&quot;.&quot;</td>
<td>Decimal mark for numbers (&quot;.&quot; or &quot;,&quot;).</td>
</tr>
<tr>
<td>row.names=1</td>
<td>The first column of the file gives the individuals' names. If this is not the case, simply omit this argument.</td>
</tr>
</tbody>
</table>

When using the function `read.table()`, you will need to specify the value of the argument `file` which must contain, in a character string, the name of the file and its complete path. You might have noticed that we used the function `file.choose()`, which opens up a dialog window to select a file and returns the required character string. This is an easy method to get the path to a file, but the path can also be specified explicitly:

```r
my.data <- read.table(file="C:/MyFolder/data.txt")
```
2.1 Importing data 63

Warning
Note that file paths are specified using slashes (/). This notation comes from the UNIX environment. In R, you cannot use backslashes (\), as you would in Microsoft Windows, unless you double all the backslashes (\\).

Another option is using the function `setwd()` to change the work directory (equivalent to using the menu “File/Change current directory”). The argument `file` will then accept the file name alone, without its path.

```r
setwd("C:/MyFolder")
my.file <- "mydata.txt"
data <- read.table(file=my.file)
```

Your data are now available in the R console: they are stored in the object which you have chosen to call `data`. You can visualize them by typing `data`; you can also type `head(data)` or `tail(data)` to display only the beginning or the end of the dataset.

Tip
- The function `attach()` (see Chapter 7) gives direct access to the variables (columns) of a data.frame, by typing the name of a variable as it is written on the first line of the file in ASCII format (assuming this is the case).

```r
attach(data)
```

- If your file contains completely empty lines, or incomplete lines, use the two arguments `fill=TRUE` and `blank.lines.skip=FALSE`. 
Create a folder called DataFolder. Now download the file http://www.biostatisticien.eu/springer/Intima_Media_Thickness.txt and save it in the folder DataFolder.

Use the function readLines() to visualize the beginning of the data file, to get an idea of how it is structured, and thus to determine which arguments of the function read.table() you will need.

```r
setwd("path/to/DataFolder/") # Replace path/to/ with your path.
readLines("Intima_Media_Thickness.txt",n=5)
```

You will get the following output:

```
[1] "GENDER AGE height weight tobacco packyear SPORT measure alcohol"
[2] "1 33 170 70 1 1 0 0,52 1"
[3] "2 33 177 67 2 20 0 0,42 1"
[4] "2 53 164 63 1 30 0 0,65 0"
[5] "2 42 169 76 1 26 1 0,48 1"
```

You will notice that the first line gives the variables names. Fields are separated by simple whitespace, and the decimal mark is a comma. Therefore, you need to use the arguments header=TRUE, sep=" " and dec=" ".

```r
mydata <- read.table("Intima_Media_Thickness.txt",sep=" ",header=T,dec=" ")
```

Let us now verify the structure of the object mydata and the types of its columns:

```r
class(mydata)
str(mydata)
```

The function attach() is used to enable a direct acces to the variables of the table.

```r
attach(mydata)
```

The command names(mydata) outputs variable names. You can use these to make calculations with the variables; for example:

```r
mean(AGE) # Mean age.
var(taille) # Variance of the heights.
```

Note that case (upper/lower) is important.
2.1 Importing data

The function `read.table()` takes many arguments. However, since many data sets come in a standard format, a few functions exist to read these easily. Such functions are in fact equivalent to calling `read.table()` with some arguments filled in by default.

For example, if you have a file in the `.csv` format (csv stands for *comma separated values*), created for example using OpenOffice’s spreadsheet, you can also use the following function:

```r
read.csv(file.choose()) # To read comma-separated data
# (with a . as decimal mark).
read.csv2(file.choose()) # To read semi-colon-separated data
# (with a , as decimal mark).
```

To read Tab-separated data, it is better to use:

```r
read.delim(file.choose()) # (with a . as decimal mark).
read.delim2(file.choose())# (with a , as decimal mark).
```

#### 2.1.1.2 Reading data with `read.ftable()`

Sometimes, individual data are not available: instead, we only have a contingency table. In this case, the relevant import function is `read.ftable()`.

For instance, suppose that the contents of the file `Intima.ftable.txt` come in the following form:

```
"alcohol" "nondrinker" "occasional drinker" "regular drinker"
"GENDER" "tobacco"
"M" "non-smoker" 6 19 7
"former smoker" 0 9 0
"smoker" 1 6 5
"F" "non-smoker" 12 26 2
"former smoker" 3 5 1
"smoker" 1 6 1
```
The following functions can be used to read and display these data in R:

```r
Intima.table <- read.ftable("Intima_ftable.txt", row.var.names=c("GENDER","tobacco"), col.vars=list("alcohol"=
c("nondrinker","occasional drinker","regular drinker")))
ftable(Intima.table)
```

The output will then be:

```
alcohol nondrinker occasional drinker regular drinker
GENDER tobacco
M non-smoker 6 19 7
  former smoker 0 9 0
  smoker 1 6 5
F non-smoker 12 26 2
  former smoker 3 5 1
  smoker 1 6 1
```

See also

We shall present a descriptive analysis of this type of data in Chapter 9, pages 344, 351 and 371. Note that standard statistical tests on contingency tables are possible, such as the chi-squared independence test presented in Chapter 11, page 434. You may also be interested in the article [http://www.jstatsoft.org/v17/i03/paper](http://www.jstatsoft.org/v17/i03/paper) which presents several tools to analyse such data.

2.1.1.3 Reading data with the function `scan()`

The function `scan()` takes many arguments. It is useful when the data are not organized as a rectangular table. We recommend you read the documentation `help(scan)`.

For example, suppose your data file, called `Intima_Media2.txt`, contains the following lines:

```
File description:
-----------------------
The individual data are registered for nine variables
in the following order:
GENDER AGE height weight tobacco packyear SPORT measure alcohol
Data:
--------
1 33 170 70 1 1 0 0,52 1 2 33 177 67 2 20 0 0,42 1
2 53 164 63 1 30 0 0,65 0 2 42 169
76 1 26 1 0,48 1
```

Here are the commands we suggest you use to read this file. The argument `skip=n` is used to omit reading the first `n` lines of the file.

```r
# Reading variable names:
variable.name<-scan("Intima_Media2.txt",skip=5,nlines=1,what="")
```
# Reading data:
data <- scan("Intima_Media2.txt",skip=9,dec=" ")
mytable <- as.data.frame(matrix(data,ncol=9,byrow=T))
colnames(mytable) <- variable.name

Here is the output:

<table>
<thead>
<tr>
<th>GENDER</th>
<th>AGE</th>
<th>height</th>
<th>weight</th>
<th>tobacco</th>
<th>packyear</th>
<th>SPORT</th>
<th>measure</th>
<th>alcohol</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>33</td>
<td>170</td>
<td>70</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>0.52</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>33</td>
<td>177</td>
<td>67</td>
<td>2</td>
<td>20</td>
<td>0</td>
<td>0.42</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>53</td>
<td>164</td>
<td>63</td>
<td>1</td>
<td>30</td>
<td>0</td>
<td>0.65</td>
<td>0</td>
</tr>
<tr>
<td>4</td>
<td>42</td>
<td>169</td>
<td>76</td>
<td>1</td>
<td>26</td>
<td>1</td>
<td>0.48</td>
<td>1</td>
</tr>
</tbody>
</table>

**Tip**

Note that the functions `read.table()` and `scan()` can also be used to read online ASCII files directly from the Internet.

`read.table("http://www.biostatisticien.eu/springeR/temperature.dat")`

### 2.1.2 Importing data from Excel or the Open Office spreadsheet

#### 2.1.2.1 Copy-pasting

Using the mouse, select the range of the data (in the spreadsheet) which you wish to incorporate into R. Once the data are selected, copy them to the clipboard (from the Edit menu, or with the keyboard shortcuts CTRL+C on Windows or COMMAND+C on a Mac).

All you need to do now is type the following instructions in the R console to transfer the data from the clipboard.

`x <- read.table(file("clipboard"),sep=" \t",header=TRUE,dec=" ","")`

**Tip**

The instruction `fix(x)` opens a small spreadsheet in R, which can be used to visualize and edit the data stored in x. It is more useful than the command `edit`, which only allows modifications. Similarly, the function `View()` displays the data in a small spreadsheet, but cannot be used to edit them.
Warning

Be aware that the Excel file might include formulae or other hidden characters in the data range which you wish to copy. A possible workaround is to first copy, then do a special paste of this data range in a new sheet of the Excel file. You can then use the function `read.table()` on this new sheet, as indicated above.

2.1.2.2 Using an intermediary ASCII file

Save your file in an ASCII format, then refer to the previous section.

- Under Excel, go to `File / Save as ...` and choose `Data type: Text (tab-separated) (*.txt)` (*.txt) then save.
- Under OpenOffice, go to `File / Save as ...` and choose `File type: CSV text (.csv; .txt)` then save.
  In the next window, choose:
  - field separator: Tab
  - text separator: "
  then click OK.

2.1.2.3 Using specialized packages

A few packages exist to read `.xls` files directly in R. One function worth mentioning is `read.xls()` from the package `gdata`, which works very well, as long as your computer has PERL installed (this free software can be obtained by installing the file http://www.biostatisticien.eu/springeR/Rtools29.exe). You can also use the package `xlsReadWrite`.

2.1.3 Importing data from SPSS, Minitab, SAS or Matlab

The following table gives the packages and R functions you can use to import data from common proprietary software.

The function `lookup.xport()` outputs (as a list) information on the SAS library of a SAS XPORT file (extension *.xpt).
2.1 Importing data

Table 2.3: Packages and R importation functions from common software.

<table>
<thead>
<tr>
<th>Software</th>
<th>Package</th>
<th>R function</th>
<th>File extension</th>
<th>Output format</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPSS</td>
<td>foreign</td>
<td>read.spss()</td>
<td>*.sav</td>
<td>list</td>
</tr>
<tr>
<td>Minitab</td>
<td>foreign</td>
<td>read.mtp()</td>
<td>*.mtp</td>
<td>list</td>
</tr>
<tr>
<td>SAS</td>
<td>foreign</td>
<td>read.xport()</td>
<td>*.xpt</td>
<td>data.frame</td>
</tr>
<tr>
<td>Matlab</td>
<td>R.matlab</td>
<td>readMat()</td>
<td>*.mat</td>
<td>list</td>
</tr>
</tbody>
</table>

Warning

First, note that if you use Windows, the package foreign is pre-installed (but not loaded) in R and that you cannot install another version from the CRAN (only Linux and Mac versions are available).

Also note the following caveats. The function read.spss() can require the argument reencode="utf8" under Linux. The function read.mtp() works on files containing only numeric data. At the time of writing, the function read.xport() cannot be used to read files directly from the Internet.

2.1.4 Large data files

R can handle large data sets. For this, you need to specify explicitly the type of each column. If you do not, R will have to read the entire file to check that numeric columns are indeed numeric (it could be the case that a column contain numbers at the beginning, then character strings later on). The following example illustrates this point with genomic data, well-known for their large size. You will need to download the file http://www.biostatisticien.eu/springeR/dbsnp123.dat to your computer, then try the instructions below.

Warning

Be careful that if you issue the commands below, this will freeze your R session for a few minutes.

tm <- Sys.time() # Gets the current time.
dbsnp <- read.table("dbsnp123.dat")
Sys.time()-tm
Time difference of 5.063645 mins

tm <- Sys.time()
dbsnp<read.table("dbsnp123.dat", colClasses=rep("character",3))
Sys.time()-tm
Time difference of 13.75810 secs
Very big data sets can thus be handled by R relatively quickly, when the correct instructions are given. The main limit is how much RAM you have available. Note also that using the function `scan()` instead of `read.table()` in the previous example would give similar execution times.

Large data sets are sometimes stored in binary format. In that case, the function `readBin()` can be used to read the data. We shall see an example in the practical of Chapter 5.

If R displays a message indicating a failure of memory, you could consult with profit section 7.8.

**Advanced users**

If the function `scan()` is used correctly, a text file can be read very quickly (as quickly as with the SAS software, for example).

If your file is really big, you should consider storing your data in a database (for example MySQL) and accessing them piece by piece. See section 2.4 for more details.

Also note that several packages exist to handle large data sets: R.huge and filehash. The latter is more general than the former: with the filehash package, the limit to the size of data which can be handled is the size of the hard disk.

### SECTION 2.2 Exporting data

#### 2.2.1 Exporting data to an ASCII text file

The relevant function is `write.table()`.

Suppose you have a data frame called `mydata`, containing data that you wish to save in a text file. You would then use the instruction:

```r
write.table(mydata, file = "myfile.txt", sep = "\t")
```
2.3 Creating data

There also exists a function `write()`, which is used on vectors and matrices. This function has an interesting argument: `ncolumns` allows you to specify the number of columns in the resulting file. Note however that the file will contain the transpose of the matrix or vector you are writing.

2.2.2 Exporting data to Excel or OpenOffice Calc

For example, type the following instructions in the R console:

```r
X <- data.frame(Weight=c(80,90,75),Height=c(182,190,160))
write.table(X,file("clipboard"),sep="\t",dec=",".,row.names=FALSE)
```

The data have now been copied to the clipboard. You can now paste them in your spreadsheet, for example by typing CTRL+V.

You can also use the package `xlsxReadWrite` (only under Windows).

### SECTION 2.3

**Creating data**

2.3.1 Entering toy data

This section shows how you can quickly create some data. This is useful when you need to test various R functions on small data sets.

The main functions are `c()`, `seq()`, `:` and `rep()`.

- The function `c()` is used to create a vector by concatenating its arguments.

```r
> c(1,5,8,2.3)
[1] 1.0 5.0 8.0 2.3
```

- The function `seq()` generates a sequence of values as a vector.

```r
> seq(from=4,to=5)
[1] 4.0
> seq(from=4,to=5,by=0.1)
[1] 4.0 4.1 4.2 4.3 4.4 4.5 4.6 4.7 4.8 4.9 5.0
> seq(from=4,to=5,length=8)
```
The last two functions can also be used to create character strings.

- The function ":"() generates a sequence of integers.

```
> 1:12
[1]  1  2  3  4  5  6  7  8  9 10 11 12
```

- The function `rep()` replicates the values of its first argument in several smart ways. We leave it to the sagacity of the reader to understand all the following instructions.

```
> rep(1,4)
[1] 1 1 1 1
> rep(1:4, 2)
[1] 1 2 3 4 1 2 3 4
> rep(1:4, each = 2)
[1] 1 1 2 2 3 3 4 4
> rep(1:4, c(2,1,2,3))
[1] 1 1 2 3 3 4 4
> rep(1:4, each = 2, len = 4)
[1] 1 1 2 2
> rep(1:4, each = 2, len = 10)
[1] 1 1 2 2 3 3 4 4 1 1
> rep(1:4, each = 2, times = 3)
[1] 1 1 2 2 3 3 4 4 1 1 2 2 3 3 4 4 1 1 2 2 3 3 4 4
```

### 2.3.2 Generating pseudo-random numbers

The function `runif()` generates a sequence of randomly generated numbers (at uniform).

```
> runif(5)
[1] 0.4344968 0.7153407 0.4561363 0.9580362 0.7260245
> runif(5, min=2, max=7)
[1] 5.634204 4.046403 5.415685 5.251441 2.209174
```

The function `rnorm()` generates a sequence of random numbers from a normal distribution.

```
> rnorm(5)
[1] 0.13585341 -0.09483162 -2.12326103 0.45974393 1.29587671
> rnorm(5, mean=2, sd=3)
[1] -0.8673785 3.5660222 0.9401026 3.4794672 4.2175481
```

See also

We shall encounter many other similar functions in Chapter 10, page 405.
2.3 Creating data

2.3.3 Entering data from a hard copy

• Creating a vector with the function scan()

In this context, `scan()` is more user-friendly than `c()`. It can be used to easily enter data as you go.

```r
> z <- scan() # R is waiting for you to enter data.
1: 4.2
2: 5.6
3: 8.9
4: 1
5: 2.3
# Press ENTER after an empty line
# to halt the procedure.
Read 5 items
> z
[1] 4.2 5.6 8.9 1.0 2.3
```

• Creating several vectors of different lengths

The function `data.entry()` is useful for this purpose. This function does not output anything. The variables you enter by hand are stored in the small spreadsheet which is displayed.

```r
# The following instruction (which is explained later on)
# can be used to delete all the objects in the session.
rm(list=ls())
data.entry(""")
```

You can now change the names of the variables (columns) and enter data. Columns can contain different numbers of observations. If you leave the mini spreadsheet and type in the instruction `ls()`, you will see the variables you have created.

The way this function works can vary on different operating systems.

• Creating and individual variables table

To enter data directly into R’s mini spreadsheet (as if using Excel), simply use the function `de()` (for `data entry`), as shown in the following instruction.

```r
X <- as.data.frame(de(""'))
```
Warning

Remember to change the names of the variables, as well as the types of the columns (numeric or character), by clicking on the cells on the first row of the table (the row with the variable names). Once you have finished entering your data, you need to close that window to return to the R console.

If you need to make small modifications to your data table X, simply use the function fix(): fix(X).

Tip

The following (optional) function is used to name the rows of X:

\[
\text{rownames}(X) \leftarrow \text{paste}(\text{"ind"}, 1: \text{nrow}(X), \text{sep=""})
\]

The names of the individuals will then appear in the first column of the mini spreadsheet (called row.names).

SECTION 2.4

Reading/Writing in databases

R is capable of communicating with most Database Management Systems (DBMS). In this section, we briefly look at the main operations for the DBMS MySQL.

EasyPHP is an environment with two servers (an Apache web server and a MySQL database server), a script interpreter (PHP) and a SQL administration tool (phpMyAdmin). Download, install and run the latest version of EasyPHP. (http://www.easyphp.org).

Note

You may need to configure your firewall so that it allows services started by EasyPHP (mysqld and Apache).

2.4.1 Creating a database and a table

Start EasyPHP and right-click on the icon on the right side of the task bar (you may need to check on the small white triangle Show hidden icons), then select
Administration. Your web browser should then open (if it does not, try using the browser firefox and configuring Apach by right-clicking on the EasyPHP icon, then Configuration: Listen 127.0.0.1:80). On the page that opens up, check on the open button in section MODULES to get to the phpMyAdmin administration page. Then click on the tab Databases and create a new database called BMI. Click on the icon Create table which appears in the left panel.

Then give a name to the table: mytable.

Define four fields for your table (one per line), and fill them as follows:

- **Name**=FirstName, **Type**=VARCHAR and **Length/Values**=20;
- **Name**=Weight, **Type**=FLOAT and **Length/Values**=3;
- **Name**=Height, **Type**=FLOAT and **Length/Values**=3;
- **Name**=BMI, **Type**=FLOAT and **Length/Values**=5.

Click on Save.

### 2.4.2 Creating a data source compatible with MySQL

The functions odbcConnect(), sqlQuery() and odbcClose() from package RODBC are useful to handle databases from different systems (PostgreSQL, MySQL, etc.) through R thanks to an ODBC (Open DataBase Connectivity) link created with an existing database. Under Windows, here is how you create an ODBC data source compatible with MySQL.

First install MyODBC (MySQL Connector/ODBC) (http://dev.mysql.com/downloads/connector/odbc). Next, in order to display the window Data source (ODBC), you will have to execute the file C:\Windows\System32\odbcad32.exe.

**Tip**

For a 64 bit computer, you may need to use file C:\Windows\Syswow64\odbcad32.exe.

Click on Add and select entry MySQL ODBC 5.1 Driver. In the windows which opens up, enter the following fields:

- **Data Source Name**: dsnBMI
- **TCP/IP Server**: 127.0.0.1 Port: 3306
- **User**: root
- **Database**: BMI

Then click on button Test. The message **Connection successful** should appear if everything happened correctly. Then click on OK (twice) to close the dialog boxes.
We have thus configured an ODBC link which will allow R to communicate with MySQL.

Check that the file `/etc/odbcinst.ini` includes references to the drivers of the MySQL database. You also need to modify (as root) the file `/etc/odbc.ini` so that it includes the following lines:

```ini
[dsnBMI] # name of the data source.
Description =
Driver = MySQL
Server = localhost
Database = BMI
Port = 3306
```

### 2.4.3 Writing in a table

We shall now write information in table `mytable` of base BMI. The following instruction are used to add the weight, height and BMI (temporarily set at 0) for an individual named Peter.

```r
> require(RODBC)
> Connection <- odbcConnect(dsn="dsnBMI",uid="root",pwd="")
> request <- "INSERT INTO mytable VALUES ('Peter',72,182,0)"
> result <- sqlQuery(Connection,request)
> odbcClose(Connection)
```

Here is now a multiple insertion example.

```r
> FirstNames <- c("Ben","John")
> Weight <- c(70,75)
```
2.4.4 Reading a table

To read from R information in the table `mytable`, you can use the following instructions.

```r
> require(RODBC)
> Connection <- odbcConnect(dsn="dsnBMI",uid="root",pwd="")
> request <- "SELECT * FROM mytable"
> data <- sqlQuery(Connection,request)
> odbcClose(Connection)
> data
  FirstName Weight Height BMI
1  Peter     72    182  0.000
2    Ben     70    190 19.391
3   John     75    184 22.153
```

Tip

You can return to phpMyAdmin to check that the table `mytable` has indeed been modified (tab `Browse`).
Memorandum

read.table(): read a rectangular data file
scan(): read data line by line
read.ftable(): read a contingency table
ftable(): display a contingency table
readLines(): read and display a few lines of a file
file.choose(): open a dialogue window to select a file
file.header, sep, dec, row.names, skip: main arguments of read.table()
read.spss(), read.mtp(), read.xport(), readMat(): import data from other software
write.table(): write a data file
file("clipboard"): copy from or paste to the clipboard
c(): create a sequence of elements of the same nature
seq(): create a sequence of numbers or a character string
rep(): repeat the values of the first argument
de(), data.entry(): enter data using a mini spreadsheet
fix(): modify a data.frame or a matrix in a mini spreadsheet

Exercises

2.1- Name the three main R functions to import data from an ASCII text file.
2.2- One of the usual data reading functions takes the following arguments: header, sep, dec, row.names, skip, nrows. Explain their purpose. Give an example of a value each argument can take.
2.3- What is the purpose of the function readLines()?
2.4- What is the purpose of the function fix()?
2.5- Give the specificities of the functions read.csv(), read.csv2(), read.delim() and read.delim2().
2.6- What is the purpose of the function read.ftable()?
2.7- What is the difference between the functions scan() and read.table()?
2.8- Explain how you would import data from an Excel spreadsheet. Give details.
2.9- Which package includes several functions to import data from commercial statistical software?
2.10- When reading a large data file, which argument to the function read.table() can speed up the reading?
2.11- Which R function should be used to write to a file a data set contained in a data.frame? Which other function do you know?
2.12- Name the four basic functions to create a vector.
2.13- Explain how the function seq() can be used to get the following vector:
[1] 1.0 1.1 1.2 1.3 1.4 1.5 1.6 1.7 1.8 1.9 2.0
2.14- Give the shortest R instruction which outputs the following vector:

1 1 2 2 3 3
2.15- Give the shortest R instruction which outputs the following vector:

\[ 1 \ 2 \ 3 \ 1 \ 2 \ 3 \]

2.16- Name two R functions which can be used to enter data by hand in a mini spreadsheet.

---

**Worksheet**

**Reading various data sets**

**A- Entering data from a hard copy**

- Fever blisters: Thirty patients have been randomly assigned to one of five treatments against fever blisters, including one placebo (there are six patients in each treatment group). For each patient, the number of days between the apparition of the first blisters and complete healing has been recorded.

<table>
<thead>
<tr>
<th>Treatments</th>
<th>trt1 (placebo)</th>
<th>trt2</th>
<th>trt3</th>
<th>trt4</th>
<th>trt5</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>5</td>
<td>8</td>
<td>7</td>
<td>7</td>
<td>10</td>

</tbody>
</table>

We would like to know whether there is a difference between the treatments, by comparing the mean healing time in each independent random sample (treatment group). The relevant statistical method is called ANOVA; we shall present it in Chapter 13. In this practical, we shall simply see how to enter these data in R to compute the sample mean for each treatment.

2.1- Enter the data in R directly, using the function `de()`.  
2.2- Use the function `attach()` , then the function `mean()` to compute the mean for each treatment.  
2.3- Compute the means of all treatments simultaneously thanks to the function `colMeans()`.  
2.4- Use the function `write.table()` to save your data.frame in a file called `blisters.txt`.  
2.5- Open your file in a text editor and check that there was no problem.  
2.6- Use the function `rm()` to delete all the R objects you have created in your work environment.
2.7- Import the file `blisters.txt` with the function `read.table()` and display the data.

- **Risk factors for atherosclerosis:** As part of a study on risk factors for atherosclerosis, data were collected and are summed up in this contingency table:

<table>
<thead>
<tr>
<th>GENDER</th>
<th>tobacco</th>
<th>alcohol</th>
<th>occasional-drinker</th>
<th>regular-drinker</th>
</tr>
</thead>
<tbody>
<tr>
<td>M</td>
<td>non-smoker</td>
<td>6</td>
<td>19</td>
<td>7</td>
</tr>
<tr>
<td></td>
<td>former smoker</td>
<td>0</td>
<td>9</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td>smoker</td>
<td>1</td>
<td>6</td>
<td>5</td>
</tr>
<tr>
<td>F</td>
<td>non-smoker</td>
<td>12</td>
<td>26</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>former smoker</td>
<td>3</td>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>smoker</td>
<td>1</td>
<td>6</td>
<td>1</td>
</tr>
</tbody>
</table>

It would be interesting to know whether there is a dependence between smoking and drinking, according to gender. To enter these data in R, there are several steps.

2.1- Use the function `scan()` to get a matrix $X$ of size $6 \times 3$. This matrix will contain the data only.
2.2- Use the instruction `class(X) <- "ftable"` to specify that it is a contingency table.
2.3- Type the two instructions:

```r
attributes(X)$col.vars <- list(alcohol=c("nondrinker","occasional-drinker","regular-drinker"))
attributes(X)$row.vars <- list(GENDER=c("M","F"),tobacco=c("non-smoker","former smoker","smoker"))
```
2.4- Display the contingency table you have created.
2.5- Use the function `write.ftable()` to save the contingency table in a file called `athero.txt`.
2.6- Open the file in a text editor and check that there was no problem.
2.7- Use the function `rm()` to delete all the R objects you have created in your work environment.
2.8- Import the file `athero.txt` with the function `read.table()` and display the data.

**B- Importing from other software**

During a study of BMI (Body Mass Index) of children, a team of statisticians collected data in different formats. As an exercise, we are going to read these various formats. There are several files called `bmichild`, but with different file extensions.

2.1- Import the file `bmichild.xls` into a data.frame called `bmi.XLS`.
2.2- Import the file `bmichild.xpt` into a data.frame called `bmi.SAS`.
2.3- Import the file `bmichild.sav` into a data.frame called `bmi.SPSS`.
2.4- Import the file `bmichild.mat` into a data.frame called `bmi.MAT`. The procedure is trickier for this file, so here are detailed instructions:
2.4

```r
x <- readMat("bmichild.mat")
class(x) # x is a list
x      
  # you can see that the data are in $bmi[,,1]
x <- x$bmi[,,1]
  # Note that the elements of GENDER and zep
  # are recorded in a list.
x$GENDER
class(x$GENDER) <- "character"
x$GENDER
class(x$zep) <- "character"
bmi.MAT <- as.data.frame(x)
```

2.5- To check that there was no problem during importation, use the function `summary()` on all these `data.frames`. This will display a few numerical summaries.

2.6- All these `data.frames` are identical. Save one of them in a file called `bmichild.txt`.

C- Importing more complex data files

Statisticians often encounter data files in non-standard formats. This section therefore provides training in reading several non-standard files on which we wish to perform statistical analysis.

2.1- Import the file `raf98.gra` into the most relevant structure. To this end, you will need to read the associated file `geoidformat.txt` which describes the file format.

2.2- Import the file `Infarction.xls` into a `data.frame`. Make sure you handle missing values correctly.

2.3- The file `nutrition_elderly.txt` contains thirteen variables measured on 226 individuals. Import the file into a `data.frame` (hint: use the functions `t()` and `as.data.frame()`).

2.4- The file `Birth_weight.txt` contains ten variables measured on 189 individuals. Import it into a `data.frame`, which will contain the names of the variables as well as the names of the individuals (these are available in the column `Id`). Remember that you can use the online help!
Chapter 3
Data manipulation, functions

Prerequisites and goals

• First, read Chapters 1 and 2.
• In this chapter, we shall present elementary data manipulation functions. We shall also describe the main control structures, and show how to use the object component extraction tool. This is a very powerful method, which you will need in order to use R in the most efficient way. We shall present direct extraction and extraction by logical mask. We shall also explain how to handle character strings and dates in R.

SECTION 3.1
Operations on vectors, matrices and lists

3.1.1 Vector arithmetic

One of the advantages of R is that it can operate on vectors and matrices. For example, the instruction

```r
> x <- c(1, 2, 4, 6, 3)
> y <- c(4, 7, 8, 1, 1)
> x+y
[1] 5 9 12 7 4
```

returns, in a single operation, the vector of sums \(x_1 + y_1, \ldots, x_n + y_n\).
This is one of the **main strengths** of R. It is called vectorization. You should get used to working in this fashion. Thus, you should **avoid using programming loops**, as is often done in other languages: such code would run much slower.

R operates in a similar fashion for many functions, such as: +, *, -, /, exp, log, sin, cos, tan, sqrt, and so on.

For example, the following instruction calculates the exponential of all the elements of the matrix $M$:

```r
> M <- matrix(1:9,nrow=3)
> exp(M)
```

```
[,1]       [,2]      [,3]
[1,] 2.718282 54.59815 1096.633
[2,] 7.389056 148.41316 2980.958
[3,] 20.085537 403.42879 8103.084
```

### 3.1.2 Recycling

At this stage, it is important to note how R behaves when given an operation on two vectors of different lengths. R will complete the shortest vector, reusing the values of this vector. The following example should help understand this concept:

```r
> x <- c(1,2,3,4,5,6,7,8,9,10,11,12,13,14,15) # Vector of length 15.
> y <- c(1,2,3,4,5,6,7,8,9,10) # Vector of length 10.
> x+y # Vector of length 15.

[1]  2  4  6  8 10 12 14 16 18 20 12 14 16 18 20
```

R has completed the vector y thus: `c(1,2,3,4,5,6,7,8,9,10,1,2,3,4,5)` by reusing its values, in a circular fashion.

This behaviour is called **recycling**. It is important that you be aware of this behaviour, since it can provoke hard-to-detect errors. As a matter of fact, R usually displays a warning:

*Warning message:*  
*In x + y:*
3.1 Operations on vectors, matrices and lists

Here is another example of recycling, this time used to create a matrix. The vector 1:4 is reused in a circular fashion to fill in the matrix, which is declared to be of size 3 x 3.

```r
> matrix(1:4, ncol=3, nrow=3)
[,1] [,2] [,3]
[1,] 1 4 3
[2,] 2 1 4
[3,] 3 2 1
```

3.1.3 Basic functions

Here are a few basic data manipulation functions. These are used very often; it is essential that you know them.

- `length()`: returns the length of a vector.
  ```r
  > length(c(1,3,6,2,7,4,8,1,0))
  [1] 9
  ```

- `sort()`: sorts the elements of a vector, in increasing or decreasing order.
  ```r
  > sort(c(1,3,6,2,7,4,8,1,0))
  [1] 0 1 1 2 3 4 6 7 8
  > sort(c(1,3,6,2,7,4,8,1,0), decreasing=TRUE)
  [1] 8 7 6 4 3 2 1 1 0
  ```

- `rev()`: rearranges the elements of a vector in reverse order.
  ```r
  > rev(c(1,3,6,2,7,4,8,1,0))
  [1] 0 1 8 4 7 2 6 3 1
  ```

- `order()`, `rank()` : the first function returns the vector of (increasing or decreasing) ranking indices of the elements. The second function returns the vector of ranks of the elements. In case of a tie, the ordering is always from left to right.
  ```r
  > vec <- c(1, 3, 6, 2, 7, 4, 8, 1, 0)
  > names(vec) <- 1:9
  > vec
  1 2 3 4 5 6 7 8 9
  1 3 6 2 7 4 8 1 0
  > sort(vec)
  9 1 8 4 2 6 3 5 7
  0 1 2 3 4 6 7 8
  ```
> order(vec)
[1] 9 1 8 4 2 6 3 5 7
> rank(vec)
 1 2 3 4 5 6 7 8 9
2.5 5.0 7.0 4.0 8.0 6.0 9.0 2.5 1.0

- `unique()` as the name suggests, this function removes the duplicates of a vector.

  > unique(c(1,3,6,2,7,4,8,1,0))
  [1] 1 3 6 2 7 4 8 0

- `duplicated()` indicates elements which have already been encountered earlier in the vector (read from left to right).

  > duplicated(c(1,3,6,2,7,4,8,1,0))
  [1] FALSE FALSE FALSE FALSE FALSE FALSE FALSE TRUE FALSE

### 3.1.4 Operations on matrices and data.frames

We shall describe several specialized R functions which give information on a matrix (or a data.frame), or help manipulate its rows and columns.

See also

Standard matrix operations (product, decomposition, Jacobian...) are described in Chapter 8, page 314.

#### 3.1.4.1 Information on architecture

Here are a few functions which give information on a matrix or a data.frame:

- `dim()`: size of the matrix or data.frame.
- `nrow()`: number of rows.
- `ncol()`: number of columns.
- `dimnames()`: names of rows and columns (as a list).
- `names()`, `colnames()` : names of columns.
- `rownames()`: names of rows.
3.1 Operations on vectors, matrices and lists

Do it yourself

Import, into an R object called X, the data from the file http://www.biostatisticien.eu/springeR/Weight_birth.xls, and use the above functions on X. Note that the first column of the file gives the patient identifier.

3.1.4.2 Merging tables

It is often very useful to combine (merge) several matrices or data.frames. The basic functions to this end are `cbind()` to merge columns and `rbind()` to merge rows.

• Merging columns

The generic function is `cbind()`.

\[
\begin{align*}
&> \text{cbind(1:4,5:8)} \\
&\quad \begin{bmatrix}
1,1 & 1 \\
1,2 & 5 \\
2,1 & 2 \\
2,2 & 6 \\
3,1 & 3 \\
3,2 & 7 \\
4,1 & 4 \\
4,2 & 8 \\
\end{bmatrix}
\end{align*}
\]

However, this function is not optimal, as the following example shows. Let us try to merge in columns the two following tables.

\[
\begin{align*}
\text{X1} &= \begin{array}{ccc}
\text{Id} & \text{GENDER} & \text{Weight} \\
1 & M & 75 \\
2 & F & 68 \\
3 & F & 48 \\
4 & M & 72 \\
\end{array} \\
\text{X2} &= \begin{array}{ccc}
\text{Id} & \text{GENDER} & \text{Height} \\
1 & M & 182 \\
2 & F & 165 \\
3 & F & 160 \\
4 & M & 178 \\
\end{array}
\end{align*}
\]

\[
\begin{align*}
&> \text{X1} \leftarrow \text{data.frame(Id=1:4,GENDER=c("M","F","F","M"),} \\
&\quad \text{Weight=c(75,68,48,72))} \\
&> \text{X2} \leftarrow \text{data.frame(Id=1:4,GENDER=c("M","F","F","M"),} \\
&\quad \text{Height=c(182,165,160,178))} \\
&> \text{cbind(X1,X2)} \\
\end{align*}
\]

\[
\begin{align*}
\text{Id} & \text{GENDER} \text{ Weight} & \text{Id} & \text{GENDER} \text{ Height} \\
1 & M & 75 & 1 & M & 182 \\
2 & F & 68 & 2 & F & 165 \\
3 & F & 48 & 3 & F & 160 \\
4 & M & 72 & 4 & M & 178 \\
\end{align*}
\]
This works, but it is a shame that the columns Id and GENDER are duplicated. A very useful function in this context is `merge()`:

```r
> merge(X1,X2)
Id  GENDER  Weight  Height
1  1    M       75     182
2  2    F       68     165
3  3    F       48     160
4  4    M       72     178
```

Now suppose that the individuals are not sorted in the same way in both tables.

```r
> X1 <- data.frame(Id=c(1,2,3,4),GENDER=c("M","F","F","M"),
                  Weight=c(75,68,48,72))
> X3 <- data.frame(Id=c(2,1,4,3),GENDER=c("F","M","M","F"),
                  Height=c(165,182,178,160))
> merge(X1,X3)
Id  GENDER  Weight  Height
1  1    M       75     182
2  2    F       68     165
3  3    F       48     160
4  4    M       72     178
```

In this case, you cannot use the function `cbind()`, but the function `merge` still works:

```r
> merge(X1,X3)
Id  GENDER  Weight  Height
1  1    M       75     182
2  2    F       68     165
3  3    F       48     160
4  4    M       72     178
```

You will have noticed that, by default, the function `merge()` combines two data.frames. Let X and Y be the two data.frames we wish to merge, and let Z be the data.frame resulting from the merge of X and Y. The merge is based upon the columns of these two data.frames which have the same names. These columns will be called “common columns". The argument `by` can be used to specify (force) which columns are common. The value of this argument can be a vector of names, a vector of indices, or a vector of logical values. All other columns will then be treated as different columns by `merge()`, even if they bear the same name. The function `merge()` then works in the following way:

- for every row (individual) of the data.frame X, the function `merge()` compares the elements of this row to those of every row of Y, but only over the subset of common columns;
- if it finds a perfect match, it considers that it is the same individual: this individual is added to Z, then completed with the values from the non-common columns of X, then with the values from the non-common columns of Y;
- if no perfect match is found, the individual is either added to Z and completed with NA’s (if the argument `all` takes the value TRUE), or removed (if the argument `all` takes the value FALSE, which is the default value);
the operation is repeated for the next row, until the last row.

This example should help clarify things:

```r
> X <- data.frame(GENDER=c("F","M","M","F"), Height=c(165,182, 178,160), Weight=c(50,65,67,55), Income=c(80,90,60,50))
> Y <- data.frame(GENDER=c("F","M","M","F"), Height=c(165,182, 178,160), Weight=c(55,65,67,85), Salary=c(70,90,40,40), row.names=4:7)
> X
  GENDER Height Weight Income
1     F   165      50     80
2     M   182      65     90
3     M   178      67     60
4     F   160      55     50
> Y
  GENDER Height Weight Salary
4     F   165      55     70
5     M   182      65     90
6     M   178      67     40
7     F   160      85     40
> merge(X,Y,by=c("GENDER","Weight"))
  GENDER Weight Height.x Income Height.y Salary
1     F    55    160      50    165     70
2     M    65    182      90    182     90
3     M    67    178      60    178     40
> merge(X,Y,by=c("GENDER","Weight"),all=TRUE)
  Row.names Weight GENDER.x Height.x Income GENDER.y Height.y Salary
1        1     50      F    165      50     80     80
2        2     55      F    165      50     90     90
3        3     85      NA     160     50     60     60
4        4     65      M    182      90    182    182
5        5     67      M    178      60    178    178
Warning
You will have noticed that, by default, the function merge does not take into account the names of the individuals in the data.frames X and Y, when determining the common individuals. The names of the individuals can be included either by adding a column Id to X and Y to identify the individuals, or by using the name "row.names" as the value of the argument by.

> merge(X,Y,by=c("row.names","Weight"))
  Row.names Weight GENDER.x Height.x Income GENDER.y Height.y Salary
1        1     50      F    165      50     80     80
2        2     55      F    165      50     90     90
3        3     85      NA     160     50     60     60
4        4     65      M    182      90    182    182
5        5     67      M    178      60    178    178
```
• Merging lines

The generic function is `rbind()`.

```r
> rbind(1:4, 5:8)
[1,] 1  2  3  4
[2,] 5  6  7  8
```

The function `smartbind()` from the package `gtools` is more sophisticated, as shown in the following example:

```r
> require(gtools)
> df1 <- data.frame(A=1:5, B=LETTERS[1:5]) # The square brackets [] to extract
> df2 <- data.frame(A=6:10, E=letters[1:5]) # elements are described in section 3.5.
> smartbind(df1, df2)
A B E
1.1 1 A <NA>
1.2 2 B <NA>
1.3 3 C <NA>
1.4 4 D <NA>
1.5 5 E <NA>
2.1 6 <NA> a
2.2 7 <NA> b
2.3 8 <NA> c
2.4 9 <NA> d
2.5 10 <NA> e
```

Tip

The package `gdata` includes several very interesting functions to manipulate data.
3.1 Operations on vectors, matrices and lists

3.1.4.3 The function apply()

An oft-used function is apply(), which applies a given function (specified as the value of the argument FUN) to all rows (MARGIN=1) or to all columns (MARGIN=2) of a matrix or data.frame.

```
> X <- matrix(c(1:4, 1, 6:8), nr = 2)
> X
[1,] 1 3 1 7
[2,] 2 4 6 8
> apply(X, MARGIN=1, FUN=mean)
[1] 3 5
> apply(X, MARGIN=2, FUN=sum)
[1] 3 7 7 15
```

Tip
When the operation is summing or calculating the means of rows or columns, other possible functions are: rowSums(), colSums(), rowMeans(), colMeans().

**Do it yourself**

We are going to see how to calculate the sum of squares of all rows of a matrix. First, create a matrix M of size $5 \times 2$ containing numbers of your choosing. Next, use the function apply() on the rows of the matrix M. You will take the argument and associated value FUN=function(x) {sum(x^2)}.

**Warning**
In this do-it-yourself, we saw in passing how to use a self-created function (sum(x^2)) when calling apply(), by using the reserved word function. In Chapter 6, we shall explore in further detail how to create more elaborate functions.

3.1.4.4 The function sweep()

The function sweep() is very useful. It is used to “sweep out” (in a sense defined by the value of the argument FUN) a certain statistic (given by the value of the argument STATS) from every row (MARGIN=1) or from every column (MARGIN=2) of a table. The two next examples should help you understand this function.
> X

[1,]  1  3  1  7
[2,]  2  4  6  8
> # Subtract 3 from row 1, and 5 from row 2.
> sweep(X,MARGIN=1,STATS=c(3,5),FUN="-")

[1,] -2  0 -2  4
[2,] -3 -1  1  3
> # Divide the first two columns by 2, and the last two columns
# by 3.
> sweep(X,MARGIN=2,STATS=c(2,2,3,3),FUN="/"

[1,] 0.5 1.5 0.3333333 2.333333
[2,] 1.0 2.0 2.0000000 2.666667

3.1.4.5 The function stack()

The function stack() concatenates into a single vector the values of certain columns of a data.frame. This function outputs a data.frame, with the stacked vector in its first column, and a second column containing a factor which indicates the origin of each observation. The function unstack() performs the reverse operation. This function is very useful for analysis of variance (ANOVA).

> X <- data.frame(trt1=c(1,6,3,5),trt2=c(8,8,3,1))
> X

<table>
<thead>
<tr>
<th>trt1</th>
<th>trt2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>8</td>
</tr>
<tr>
<td>6</td>
<td>8</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
</tr>
</tbody>
</table>
> stack(X)

values   ind
1 1 trt1
2 6 trt1
3 3 trt1
4 5 trt1
5 8 trt2
6 8 trt2
7 3 trt2
8 1 trt2

3.1.4.6 The function aggregate()

The function aggregate() splits a data.frame into sub-populations according to a factor (specified by the argument by) and applies a given function to each sub-population.
3.1 Operations on vectors, matrices and lists

> X <- data.frame(Weight=c(80,75,60,52), Height=c(180,170,165,150), Cholesterol=c(44,12,23,34), Gender=c("Male","Male","Female","Female"))
> X
  Weight Height Cholesterol Gender
1    80    180       44  Male
2    75    170       12  Male
3    60    165       23 Female
4    52    150       34 Female
> aggregate(X[,-4],by=list(Gender=X[,4]),FUN=mean)
  Gender Weight Height Cholesterol
1 Female   56.0  157.5       28.5
2  Male    77.5  175.0       28.0

Note
The instruction X[,-4] is used to extract all the columns of X except the fourth column. Extraction instructions are explored in further detail in Section 3.4.

3.1.4.7 The function transform()

This function makes transformations on the columns of a data.frame. For example, the following example transforms the height in centimetres into the height in metres, and adds to the data.frame a column with the BMI.

> X <- transform(X, Height=Height/100, BMI=Weight/(Height/100)^2)
> X
  Weight Height Cholesterol Gender  BMI
1    80    1.80       44  Male 24.69136
2    75    1.70       12  Male 25.95156
3    60    1.65       23 Female 22.03857
4    52    1.50       34 Female 23.11111

See also
The package plyr can be used to manipulate data tables in a simple and efficient way.

3.1.5 Operations on lists

The functions lapply() and sapply() are similar to the function apply(): they apply a function to every element of a list. The former outputs a list; the latter outputs a vector if possible.
> x <- list(a = 1:10, beta = exp(-3:3), logic = c(TRUE,FALSE, + FALSE,TRUE))
> lapply(x,mean)  # Mean of each element of the list.
$\text{a}$
[1] 5.5
$\text{beta}$
[1] 4.535125
$\text{logic}$
[1] 0.5
> lapply(x,quantile,probs=(1:3)/4)  # Median and quartiles of the 
# elements of the list.
$\text{a}$
25% 50% 75%
3.25 5.50 7.75
$\text{beta}$
25% 50% 75%
0.2516074 1.0000000 5.0536690
$\text{logic}$
25% 50% 75%
0.0 0.5 1.0
> sapply(x, quantile)  # Quantiles of the elements of the list.
\begin{verbatim}
a beta logic
0% 1.00 0.04978707 0.0
25% 3.25 0.25160736 0.0
50% 5.50 1.00000000 0.5
75% 7.75 5.05366896 1.0
100% 10.00 20.08553692 1.0
\end{verbatim}
> i36 <- sapply(3:6, seq)  # Creates a list of vectors.
> i36
\begin{verbatim}
[[1]]
[1] 1 2 3
[[2]]
[1] 1 2 3 4
[[3]]
[1] 1 2 3 4 5
[[4]]
[1] 1 2 3 4 5 6
\end{verbatim}
> sapply(i36, sum)  # Sum of every vector in the list.
[1] 6 10 15 21

\textbf{Tip}

The function \texttt{do.call()} takes two arguments: the first is the name of a function, and the second is the name of a list. It executes the function, taking as input the elements of the list. We shall see an example of use in the practical. We should also mention the existence of the function \texttt{mapply()}.

We shall see an example of use in the practical. We should also mention the existence of the function \texttt{mapply()}.
3.2 Logical and relational operations

The two logical values are TRUE (or T) and FALSE (or F). Also note that in R, NA is considered to be a logical constant. Logical vectors are very useful in R, for example for extracting elements by logical mask, as we shall see later on.

This table gives operators and functions which take logical values as input or output.

Table 3.1: Operators and functions which take logical values as input or output.

<table>
<thead>
<tr>
<th>Operator in R</th>
<th>Description</th>
<th>Example</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>logical()</td>
<td>Create a vector of logical values</td>
<td>logical(c(0,1))</td>
<td>F T</td>
</tr>
<tr>
<td>is.logical()</td>
<td>Is the argument a logical value?</td>
<td>is.logical(F)</td>
<td>T</td>
</tr>
<tr>
<td>x &lt; y</td>
<td>Is ( x_i &lt; y_i )?</td>
<td>c(1,4) &lt; c(2,3)</td>
<td>T F</td>
</tr>
<tr>
<td>x &gt; y</td>
<td>Is ( x_i &gt; y_i )?</td>
<td>c(1,4) &gt; c(2,3)</td>
<td>F T</td>
</tr>
<tr>
<td>x &lt;= y</td>
<td>Is ( x_i \leq y_i )?</td>
<td>c(1,4) &lt;= c(1,1)</td>
<td>T F</td>
</tr>
<tr>
<td>x &gt;= y</td>
<td>Is ( x_i \geq y_i )?</td>
<td>c(1,4) &gt;= c(1,1)</td>
<td>T T</td>
</tr>
<tr>
<td>x == y</td>
<td>Is ( x_i = y_i )?</td>
<td>c(1,4) == c(1,3)</td>
<td>T F</td>
</tr>
<tr>
<td>x != y</td>
<td>Is ( x_i \neq y_i )?</td>
<td>c(1,4) != c(1,1)</td>
<td>F T</td>
</tr>
<tr>
<td>!x</td>
<td>Negation of ( x )</td>
<td>!c(T,F)</td>
<td>F T</td>
</tr>
<tr>
<td>x &amp; y</td>
<td>Term-by-term conjunction (AND)</td>
<td>c(T,T) &amp; c(T,F)</td>
<td>T F</td>
</tr>
<tr>
<td>x</td>
<td>y</td>
<td>Term-by-term disjunction (OR)</td>
<td>c(T,T)</td>
</tr>
<tr>
<td>xor(x, y)</td>
<td>Exclusive disjunction (XOR)</td>
<td>xor(c(T,T),c(T,F))</td>
<td>F T</td>
</tr>
<tr>
<td>any(x)</td>
<td>TRUE if at least one of the ( x_i ) is TRUE</td>
<td>any(c(T,F))</td>
<td>T</td>
</tr>
<tr>
<td>all(x)</td>
<td>TRUE if all of the ( x_i ) are TRUE</td>
<td>all(c(T,F))</td>
<td>F</td>
</tr>
<tr>
<td>all.equal(x, y)</td>
<td>Is ( x_i \approx y_i ) (see the argument tolerance)</td>
<td>all.equal(0.2-0.1,0.3-0.2)</td>
<td>F T</td>
</tr>
<tr>
<td>identical(x, y)</td>
<td>TRUE if ( \forall x_i, y_i )</td>
<td>identical(1,as.integer(1))</td>
<td>T</td>
</tr>
</tbody>
</table>

Warning

Note that the two following instructions give different results:

```r
> all.equal(0.2-0.1, 0.3-0.2)
[1] TRUE
> (0.2-0.1) == (0.3-0.2)
[1] FALSE
```

This stems from the fact that the computer has a limited precision for its calculation. The function all.equal() takes an optional tolerance argument for rounding errors. We shall discuss this further in the section on conditional instructions. See also section 3.9 that explains why the second instruction above returns FALSE.
SECTION 3.3

Operations on sets

R can handle all usual operations on sets.

> A <- c(4,6,2,7) # A first set.
> B <- c(2,1,7,3) # A second set.
> vec <- c(2,3,7) # A few elements.

<table>
<thead>
<tr>
<th>Operation</th>
<th>R Instruction</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>Membership: ( a \in A )</td>
<td><code>is.element(vec,A)</code></td>
<td>(T\ F\ T)</td>
</tr>
<tr>
<td>Inclusion (subset): ( A \subset B )</td>
<td><code>all(A %in% B)</code></td>
<td>(F)</td>
</tr>
<tr>
<td>Superset: ( A \supset B )</td>
<td><code>all(B %in% A)</code></td>
<td>(T)</td>
</tr>
<tr>
<td>Intersection: ( A \cap B )</td>
<td><code>intersect(A,B)</code></td>
<td>(2 7)</td>
</tr>
<tr>
<td>Union: ( A \cup B )</td>
<td><code>union(A,B)</code></td>
<td>(4 6 2 7 1 3)</td>
</tr>
<tr>
<td>Complement: ( A \setminus B )</td>
<td><code>setdiff(A,B)</code></td>
<td>(4 6)</td>
</tr>
<tr>
<td>Symmetric difference: ((A \cup B) \setminus (A \cap B))</td>
<td><code>setdiff(union(A,B),intersect(A,B))</code></td>
<td>(4 6 1 3)</td>
</tr>
</tbody>
</table>

Tip

It is very easy in R to define its own set functions, such as functions of inclusion, contenance and symmetric difference.

> "%inclus%" <- function(A,B) all(A %in% B)
> "%contient%" <- function(A,B) B %inclus% A
> "%diffsym%" <- function(A,B) setdiff(union(A,B),intersect(A,B))
In this section, we shall see how to extract part of a vector, matrix or list. Indeed, R includes very specific mechanisms to this effect, which can be confusing at first, but are very powerful tools.

### 3.4.1 Extracting from/Inserting into vectors

**Extraction**

To extract components from a vector, use the function `"["()`. It can take the following arguments:

- a vector of indices of elements to extract;
- a vector of indices of elements not to extract;
- a vector of logical values `TRUE/FALSE` indicating which elements to extract.

A few examples will make this easier to understand.

```r
> vec <- c(2,4,6,8,3)
> vec[2]
[1] 4
> "["(vec,2) # Note: "[" is indeed a function.
[1] 4
> vec[-2] # All elements except the second.
[1] 2 6 8 3
> vec[2:5]
[1] 4 6 8 3
> vec[-c(1,5)]
[1] 4 6 8
> vec[c(T,F,F,T,T)] # Extraction by logical mask.
[1] 2 8 3
> vec>4
[1] FALSE FALSE TRUE TRUE FALSE
> vec[vec>4] # Extraction by logical mask.
[1] 6 8
```

**Warning**

It is important to note here the syntactical simplicity of an instruction such as `x[y>0]`, which extracts from `x` all elements of index `i` such that `y_i > 0`.

```r
> x <- 1:5
> y <- c(-1,2,-3,4,-2)
```
You need to learn to use as often as possible such constructions, which are called **logical masks**. There are two advantages: the code is easy to read, and execution is very fast.

Also note the functions `which()`, `which.min()` and `which.max()`, which are often very useful.

```r
> mask <- c(TRUE, FALSE, TRUE, NA, FALSE, FALSE, TRUE)
> which(mask)  # Outputs the indices corresponding to the values
  # TRUE.
[1] 1 3 7
> x <- c(0:4,0:5,11)
> which.min(x)  # Outputs the index of the smallest value.
[1] 1
> which.max(x)  # Outputs the index of the largest value.
[1] 12
```

**Warning**

It is important to note that R does not handle index 0, unlike some other programming languages.

---

### Replacement

Replacing elements in a vector is done in a similar fashion to extraction. All you need to do is select the elements as if you wanted to extract them, then use the assignment symbol `<-` followed by the replacement elements. Of course, you need to specify the same number of replacement elements as of selected elements.

Let us examine a few examples of this principle.

```r
> z
[1] 0 0 0 2 0
> z[c(1,5)] <- 1
> z
[1] 1 0 0 2 1
> z[which.max(z)] <- 0
> z
[1] 1 0 0 0 1
> z[z==0] <- 8  # The z_i such that
  # z_i is worth 0 are replaced with
  # 8.
> z
[1] 1 8 8 8 1
```
• **Insertion**

Inserting or adding elements to a pre-existing vector uses the function `c()`.

```r
> vecA <- c(1, 3, 6, 2, 7, 4, 8, 1, 0)
> vecA
[1] 1 3 6 2 7 4 8 1 0
> (vecB <- c(vecA, 4, 1))
[1] 1 3 6 2 7 4 8 1 0 4 1
> (vecC <- c(vecA[1:4], 8, 5, vecA[5:9]))
[1] 1 3 6 2 8 5 7 4 8 1 0
```

This mechanism provides the ability to complete a vector whose size is not fixed at first.

```r
> a <- c()
> a <- c(a, 2)
> a <- c(a, 7)
> a
[1] 2 7
```

**Do it yourself**

• Create the vector `height <- c(182, 150, 160, 140.5, 191)` and the vector `gender <- c(0, 1, 1, 1, 0)` containing the height (in cm) and the gender (coded as 0=M/1=F) of five people. Extract from the vector `height` the heights of the men. Use the method of extracting by indices, then repeat the task with a logical mask.

• Extract from the following vector all numbers between 2 and 3:

```r
> x <- c(0.1, 0.5, 2.1, 3.5, 2.8, 2.7, 1.9, 2.2, 5.6)
```

### 3.4.2 Extracting from/Inserting into matrices

• **Extraction**

Two methods are possible to extract elements from a matrix `X`. Each method has its own syntax.

3.1- **Extracting by indices:** `X[indr, indc]`, where `indr` is the vector of indices of rows and `indc` is the vector of indices of columns to extract. Omitting `indr` (respectively `indc`) means that all rows are selected (respectively all columns). Note that `indr` and `indc` can be preceded by a minus sign (`-`) to indicate elements not to extract.
3.2- Extracting by logical mask: \( X[mask] \), where \( mask \) is a matrix of logical values TRUE/FALSE of the same size as \( X \), indicating which elements to extract.

Here are a few examples of the first method:

```r
> Mat <- matrix(1:12,nrow=4,ncol=3,byrow=TRUE)
> Mat
     [,1] [,2] [,3]
[1,]   1   2   3
[2,]   4   5   6
[3,]   7   8   9
[4,]  10  11  12
> Mat[2,3]  # Extracting the element at the intersection # of row 2 and column 3.
[1] 6
> Mat[,1]  # All rows, and only column 1.
[1] 1 4 7 10
> Mat[c(1,4),]  # All columns, and rows 1 and 4.
     [,1] [,2] [,3]
[1,]   1   2   3
[2,]  10  11  12
> Mat[3,-c(1,3)]  # Row 3 and column 2.
[1] 8
```

Here is an example with a logical mask:

```r
> MatLogical <- matrix(c(TRUE,FALSE),nrow=4,ncol=3)
> MatLogical  # Is of the same size as Mat.
     [,1] [,2] [,3]
[1,]  TRUE  TRUE  TRUE
[2,] FALSE FALSE FALSE
[3,]  TRUE  TRUE  TRUE
[4,] FALSE FALSE FALSE
> Mat[MatLogical]  # Make sure that you understand this # instruction.
[1] 1 7 2 8 3 9
```

Tip

It so happens that a matrix is stored in R as a long vector, the concatenation of all columns. Try for example the command `as.vector(Mat)`. Elements of a matrix can thus be extracted without using the form \([\text{rows},\text{columns}]\), but instead by using vector extraction \([\text{ind}]\) where \(\text{ind}\) is a vector of indices (or a vector of logical values) of elements to extract from the long vector.

```r
> ind
[1] 2 4 6 8 3
> Mat[ind]
[1] 4 10 5 11 7
```
Using the function "[" sometimes leads to a change in the structure of the manipulated object. Let us see this on the example below.

```r
> m <- matrix(1:6,nrow=2) ; m
[,1] [,2] [,3]
[1,] 1 3 5
[2,] 2 4 6
> m[,1]
[1] 1 2
> class(m[,1])
[1] "integer"
```

It is found that the extraction has transformed our result into a simple one row vector. This can be annoying since here one could expect to get a one column matrix. But there is a solution to this problem as the following code shows.

```r
> m[,1,drop=FALSE]
[,1]
[1,] 1
[2,] 2
```

As with vectors, the function `which()` can be used to return the indices of the elements of a matrix which verify some condition. For example:

```r
> m <- matrix(c(1,2,3,1,2,3,2,1,3),3,3)
> m
[,1] [,2] [,3]
[1,] 1 1 2
[2,] 2 2 1
[3,] 3 3 3
> which(m == 1) # m is seen as the concatenation of its columns.
[1] 1 4 8
> which(m == 1,arr.ind=TRUE) # Outputs the indices as couples.
 row col
 [1,] 1 1
 [2,] 1 2
 [3,] 2 3
```
• **Insertion**

Inserting elements into a matrix is done as with vectors. Elements are selected either by indices or with a logical mask, and are then replaced with other elements thanks to the affectation symbol `<-`.

```r
> m
[,1] [,2] [,3]
[1,]  1  1  2
[2,]  2  2  1
[3,]  3  3  3
> m[m!=2] <- 0
> m
[,1] [,2] [,3]
[1,]  0  0  2
[2,]  2  2  0
[3,]  0  0  0
> Mat <- Mat[-4,] ; Mat
[,1] [,2] [,3]
[1,]  1  2  3
[2,]  4  5  6
[3,]  7  8  9
> m[Mat>7] <- Mat[Mat>7]
> m
[,1] [,2] [,3]
[1,]  0  0  2
[2,]  2  2  0
[3,]  0  8  9
```

**Tip**

Another function can be used to extract (and therefore also to insert) elements: `subset()`. For example, try `subset(airquality, Temp > 80, select = c(Ozone, Temp))`. 
3.4 Extracting and inserting elements

Do it yourself

```r
> m1 <- matrix(c(0, 22, 0, 23, 0, 0, 0, 0, 28), ncol=3)
> m2 <- matrix(c(10, 1, 4, 10, 9, 9, 2, 6, 4), ncol=3)
> m1
 [,1] [,2] [,3]
 [1,]  0  23  0
 [2,] 22  34  0
 [3,]  0  0  28
> m2
 [,1] [,2] [,3]
 [1,] 10  10  2
 [2,]  1  9  6
 [3,]  4  9  4
```

Replace all non-zero values of `m1` with the corresponding values in `m2`.

Remove the second column from `m1`.

3.4.3 Extracting from/Inserting into arrays

Extracting from and inserting into arrays is done as with matrices, except that there can be more than two dimensions. We shall therefore only list a few examples, and leave it to the reader to check that they understand everything.

```r
> A <- array(1:12, dim=c(2, 2, 3))
> A
   [,1] [,2] [,3]
  [1,]  1  3
  [2,]  2  4
   [,1] [,2]
  [1,]  5  7
  [2,]  6  8
   [,1] [,2]
  [1,]  9 11
  [2,] 10 12
> A[2, 2, 1]
[1] 4
> A[1, 2, 3] <- 4 # Replaces 11 with 4.
> which(A==4, arr.ind=TRUE)
   dim1 dim2 dim3
 [1,]  2  2  1
 [2,]  1  2  3
> A[which(A==4, arr.ind=TRUE)]
```
3.4.4 Extracting from/Inserting into lists

- Extraction

Extracting from lists is slightly more complicated than with matrices, because each element of a list is a list itself. Using the function "["() on a list therefore outputs another list.

```
> L <- list(12, c(34, 67, 8), Mat, 1:15, list(10, 11))
> class(L)
[1] "list"
> L
[[1]]
[1] 12
[[2]]
[1] 34 67 8
[[3]]
[,1] [,2] [,3]
[1,] 1 2 3
[2,] 4 5 6
[3,] 7 8 9
[[4]]
[1] 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
[[5]]
[[5]][[1]]
[1] 10
[[5]][[2]]
[1] 11
> L[2]
[[1]]
[1] 34 67 8
> class(L[2])
[1] "list"
> L[c(3, 4)]
[[1]]
[,1] [,2] [,3]
[1,] 1 2 3
[2,] 4 5 6
[3,] 7 8 9
[[2]]
[1] 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
```

Because lists are used to store elements of different natures, the function "["() must be used to access the elements of a list.
> L[[2]]
[1] 34 67 8
> "["(L,2)
[1] 34 67 8
> class(L[[2]])
[1] "numeric"
> L[[5]][[2]]
[1] 11

Warning

The following instructions generate an error:

> L[2,3]
Error in L[2, 3] : incorrect number of dimensions
> L[[2,3]]
Error in L[[2, 3]] : incorrect number of subscripts

Advanced users

R defines what is called recursive indexing. For example, the next example starts by retrieving the content of the second element of the list L (i.e. the vector c(34, 67, 8)), then extracts the third element of this vector.

> L[c(2,3)] # Recursive indexing.
[1] 8

Furthermore, there is a mechanism in R to explicitly name the various elements of a list. The symbol $ can then be used to extract elements by name.

> L <- list(cars=c("FORD","PEUGEOT"),climate=
+ c("Tropical","Temperate"))
> L[["cars"]]
[1] "FORD" "PEUGEOT"
> L$cars
[1] "FORD" "PEUGEOT"
> L$climate
[1] "Tropical" "Temperate"

• Insertion

Inserting elements is done as previously with the arrow <-.

> L
$cars
[1] "FORD" "PEUGEOT"
$climate
[1] "Tropical" "Continental"
A column name can include spaces. To access it, you will then need to use quotation marks.

```r
> L <- list("pretty cars"=c("FORD","PEUGEOT"))
> L
$'pretty cars'
[1] "FORD"  "PEUGEOT"
> L$"pretty cars"
[1] "FORD"  "PEUGEOT"
```

### SECTION 3.5

**Manipulating character strings**

Manipulating character strings is very useful when dealing with many statistical files and when annotating graphs. We shall therefore present the major R functions in this context.

As we have seen, creating a character string is done with quotation marks "", or with the function `as.character()`.

```r
> string <- c("one","two","three")
> string
[1] "one" "two" "three"
> as.character(1:3)
[1] "1" "2" "3"
```

**Tip**

The function `noquote()` can be used to suppress the display of quotation marks in the R output.

```r
> noquote(string)
[1] one two three
```

The functions `sQuote()` and `dQuote()` are used for different styles of quotation marks.

The function `format()` is used to produce a personalized display, for example data.frames.

```r
> zz <- data.frame("First names"=c("Pierre","Benoit","Rémy"),
               check.names=FALSE)
> zz
   First names
1 Pierre
2 Benoit
```
3.5 Manipulating character strings

Other interesting functions to manage the display are `cat()`, `sprintf()` and `print()`.

The function `nchar()` counts the number of symbols in a string. It can be used on a vector of strings.

```r
> string1 <- c("a","ab","B","bba","one","!@","brute")
> nchar(string1)  # Counts the number of symbols in each string.
[1] 1 2 1 3 3 2 5
> string1[nchar(string1)>2]
[1] "bba" "one" "brute"
```

**Tip**

The commands `letters` and `LETTERS` return the twenty-six letters of the alphabet in lower and upper case.

```r
> letters
[1] "a" "b" "c" "d" "e" "f" "g" "h" "i" "j" "k" "l" "m" "n"
[15] "o" "p" "q" "r" "s" "t" "u" "v" "w" "x" "y" "z"
> string1[string1 %in% c(letters,LETTERS)]
[1] "a" "B"
```

The function `paste()` is used to concatenate several strings.

```r
> string2 <- c("e","D")
> paste(string1,string2)  # Concatenates the strings.
[1] "a e" "ab D" "B e" "bba D" "one e" "!@ D" [7] "brute e"
> paste(string1,string2,sep="-")  # A separator can be included between the strings.
[1] "a-e" "ab-D" "B-e" "bba-D" "one-e" "!@-D" [7] "brute-e"
> paste(string1,string2,collapse="",sep="")  # collapse is used to concatenate the elements into a single string.
[1] "aeabDBebbaDonee!@Dbrutee"
```

The function `substring()` is used to extract sub-strings from a string.

```r
> substring("abcdef",first=1:3,last=2:4)
[1] "ab" "bc" "cd"
```
The function \texttt{strsplit()} is used to split a string.
\begin{verbatim}
> strsplit(c("05 Jan","06 Feb"), split=" ")
[[1]]
[1] "05"  "Jan"
[[2]]
[1] "06"  "Feb"
\end{verbatim}

The function \texttt{grep()} is used to search for a pattern in a vector of strings. It returns the indices of the elements of the vector containing this pattern.
\begin{verbatim}
> grep("i",c("Pierre","Benoit","Rems"))
[1] 1 2
\end{verbatim}

The function \texttt{gsub()} replaces all occurrences of a pattern found in a string with another string.
\begin{verbatim}
> gsub("i","L",c("Pierre","Benoit","Rems"))
[1] "PLerre" "BenoLt" "Rems"
\end{verbatim}

The function \texttt{sub()} only replaces the first occurrence.
\begin{verbatim}
> sub("r","L",c("Pierre","Benoit","Rems"))
[1] "PieLre" "Benoit" "Rems"
\end{verbatim}

\textbf{Tip}

The functions \texttt{tolower()} and \texttt{toupper()} are used, respectively, to put a string into lower or upper case.
\begin{verbatim}
> tolower("loWER")
[1] "lower"
> toupper("UPper")
[1] "UPPER"
\end{verbatim}

\textbf{Do it yourself}

Input the following data.frame:
\begin{verbatim}
> X <- data.frame(date=c("03 JANUA","02 SEPTE","15 NOVEM"), +                  sun=c(10,15,12))
> X
  date  sun
1 03 JANUA 10
2 02 SEPTE 15
3 15 NOVEM 12
\end{verbatim}

Remove the first column from \texttt{X} and add in two new columns: one called day, containing the day number coded as an numeric (1 or 2 digits), and the other called month, containing the month coded as four letters in lower case (hint: use the function \texttt{transform()}).
3.6 Manipulating dates and time units

3.6.1 Displaying the current date

In R, there are two functions to display the current date: `Sys.time()` and `date()`.

```r
> Sys.time()
[1] "2013-01-09 16:04:35 EST"
> date()
```

The year, month, day, hours, minutes and seconds can be extracted as follows:

```r
> as.numeric(substring(Sys.time(),c(1,6,9,12,15,18),
+ c(4,7,10,13,16,19)))
[1] 2013 1 9 16 4 35
```

Tip

The function `system.time()` is used to find the execution time of an instruction. The function `Sys.sleep()` is used to halt the execution of a list of instructions for a given number of seconds.

3.6.2 Extracting dates

In Statistics, one often needs to extract dates from files. There are several functions in R to handle these data, which would otherwise be very difficult to manipulate.

The first useful instruction is `strptime()`, which is used to retrieve a date from a string of characters and to put it into an R object of class POSIXlt (named list of vectors containing informations on date and time).

```r
> strptime("27/mar/73",format="%d/%b/%y")
[1] "1973-03-27"
```

In the preceding instruction, you will have noted the argument `format`, which is used to describe how the date and/or time are coded in the character string. Many codes are available; we describe them in the following table.

Tip

If the previous instruction outputs `NA`, you may need to use the following instruction to change the regional parameters (`locale`) used by default by R:
Table 3.3: Codes for the function \texttt{strptime()}. The examples have been created with \texttt{format(Sys.time(),"%letter")}.

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Day of the week, abbreviated</td>
<td>Mon</td>
</tr>
<tr>
<td>%A</td>
<td>Day of the week, full name</td>
<td>Monday</td>
</tr>
<tr>
<td>%b</td>
<td>Month, abbreviated</td>
<td>Dec</td>
</tr>
<tr>
<td>%B</td>
<td>Month, full name</td>
<td>December</td>
</tr>
<tr>
<td>%c</td>
<td>Date and time, locale-specific</td>
<td>Mon 28 Dec 2018 13:06:24 CEST</td>
</tr>
<tr>
<td>%d</td>
<td>Day of the month (01-31)</td>
<td>26</td>
</tr>
<tr>
<td>%H</td>
<td>Hours (0-24)</td>
<td>13</td>
</tr>
<tr>
<td>%I</td>
<td>Hours (0-12)</td>
<td>01</td>
</tr>
<tr>
<td>%j</td>
<td>Day of the year (001-366)</td>
<td>354</td>
</tr>
<tr>
<td>%m</td>
<td>Month (01-12)</td>
<td>12</td>
</tr>
<tr>
<td>%M</td>
<td>Minutes (00-59)</td>
<td>06</td>
</tr>
<tr>
<td>%s</td>
<td>Seconds (00-61), with 2 “leap seconds”</td>
<td>24</td>
</tr>
<tr>
<td>%u</td>
<td>Week of the year (00-53); the 1st Sunday is counted as day 1 of week 1</td>
<td>51</td>
</tr>
<tr>
<td>%w</td>
<td>Day of the week (0-6); Sunday is 0</td>
<td>1</td>
</tr>
<tr>
<td>%U</td>
<td>Week of the year (00-53); the 1st Monday is counted as day 1 of week 1</td>
<td>51</td>
</tr>
<tr>
<td>%x</td>
<td>Date, locale-specific</td>
<td>2010-12-20</td>
</tr>
<tr>
<td>%X</td>
<td>Time, locale-specific</td>
<td>13:06:24</td>
</tr>
<tr>
<td>%y</td>
<td>Year without the century</td>
<td>10</td>
</tr>
<tr>
<td>%Y</td>
<td>Year with the century</td>
<td>2010</td>
</tr>
<tr>
<td>%z</td>
<td>Time off set from Greenwich; ‘-0800’ is 8 hours West of Greenwich</td>
<td>+0100</td>
</tr>
<tr>
<td>%Z</td>
<td>Time zone as a character string (output only)</td>
<td>CEST</td>
</tr>
</tbody>
</table>

Tip

Under Linux, the instruction \texttt{man strptime} typed into a terminal window can give you more codes.

\textbf{Do it yourself}

Try to read the following dates with the function \texttt{strptime()}.  

\begin{verbatim}
> dates1
[1] "3jan1948" "4jan1950" "30apr1961" "18sep1990"
\end{verbatim}

\begin{verbatim}
> dates2
[3] "07/15/99 03:01:32"
\end{verbatim}

Note that the functions \texttt{weekdays()} and \texttt{months()} can be used to retrieve the day and month of a date in the POSIXlt format.
3.6.3 Operations on dates

Before manipulating dates, you should always start by converting dates and times into objects of the class POSIXlt or POSIXct. There are two functions in R to this effect: as.POSIXct(), which gives the number of seconds elapsed since 1st January 1970 as a numeric vector, and as.POSIXlt() which is a list of vectors representing:

- sec 0-61: seconds.
- min 0-59: minutes.
- hour 0-23: hours.
- mday 1-31: day of the month.
- mon 0-11: number of months since the 1st month of the year.
- year : number of years since 1900.
- wday 0-6: day of the week, starting on Sunday.
- yday 0-365: day of the year.
- isdst : Daylight Saving Time (DST) flag. Positive if DST is observed, zero otherwise (negative if unknown).

Here are a few instructions using these functions:

```r
> z <- Sys.time() # In the POSIXct format.
> class(z) ; is.double(z)
[1] "POSIXt" "POSIXct"
[1] TRUE
> z
[1] "2013-01-09 16:04:35 EST"
> as.numeric(z) # Number of seconds since 1st January 1970.
[1] 1357765476
> # The origin can be changed:
> as.POSIXct(as.numeric(z), origin="1960-01-01")
> # About forty years have elapsed:
> as.numeric(z)/60/60/24/7/c(53,52)
[1] 42.35816 43.17274
> z <- as.POSIXlt(z) # In the POSIXlt format.
> class(z) ; is.list(z)
[1] "POSIXt" "POSIXlt"
[1] TRUE
> z
[1] "2013-01-09 16:04:35 EST"
> names(z)
[1] "sec" "min" "hour" "mday" "mon" "year" "wday"
[8] "yday" "isdst"
> z$year # Number of years since 1900.
[1] 113
```

Note that the functions as.POSIXct() and as.POSIXlt() can be used either on vectors of numeric values, or on vectors of character strings. In the former case, you will need to give a value to the argument origin, as a character string representing a date. In the latter case, each character string must be in a format such as "2001-02-03" or "2001/02/03", optionally followed by a space and a time in the
format "14:52" or "14:52:03". It might be useful to use the function `strptime()` to get a format compatible with these functions (see Table 3.3 for a description).

```r
> as.POSIXct("2001/02/03")
[1] "2001-02-03 EST"
> as.numeric(as.POSIXct("2001/02/03"))
[1] 981176400
> as.POSIXlt("2001/02/03")$wday
[1] 6
> lct <- Sys.getlocale("LC_TIME")
> Sys.setlocale("LC_TIME","C")  # See Note on page 109.
[1] "C"
> as.POSIXlt(strptime("27/mar/73",format="%d/%b/%y"))
[1] "1973-03-27"
> Sys.setlocale("LC_TIME",lct)  # To recover the locale.
[1] "fr_FR.UTF-8"
```

The class `Date` can also be used to represent dates.

```r
> z <- as.Date(c("2006-06-01", "2007-01-01"))
> class(z)
[1] "Date"
> z[1] + 100  # Add 100 days.
[1] "2006-09-09"
> z[2]-z[1]
Time difference of 214 days
> z[2] < z[1]
[1] FALSE
```

The advantage of storing dates in objects with one of the classes described above, apart from the pretty display, is that operations can then be made on these dates (difference between two dates, anteriority test...), as illustrated in the following examples.

```r
> date2 <- as.POSIXlt("2009-04-15")
> date1 <- as.POSIXlt("2000-11-24")
> date2-date1
Time difference of 3063.958 days
> difftime(date2,date1,units="hours")
Time difference of 73535 hours
> date1 <= date2
[1] TRUE
```

The package `chron` includes many functionalities to handle dates.
Like all programming languages, R includes the necessary control structures to direct the execution flow of a program.

### 3.7.1 Conditional instructions

- **Instruction `switch()`**

  It is used in the following way:

  \[
  \text{switch}(<\text{expr: test}>, <\text{expr: case }_1>=<\text{code }_1>, <\text{expr: case }_2>=<\text{code }_2>, \text{ etc.})
  \]

  In the instruction above, `<\text{expr: test}>` is either a number or a character string. This instruction outputs `<\text{code }_1>` if `<\text{expr: test}>` is equal to `<\text{expr: case }_1>`, `<\text{code }_2>` if `<\text{expr: test}>` is equal to `<\text{expr: case }_2>`, and so on. If `<\text{expr: test}>` is not equal to any of the `<\text{expr: case }_i>`s, the function `switch()` outputs `NULL`.

  Here is an example:

  ```r
  > x <- rcauchy(10)  # Generate ten random numbers from a Cauchy distribution.
  > my.input <- "mean"
  > switch(my.input, mean = mean(x), median = median(x))
  [1] -0.5472605
  > my.input <- "median"
  > switch(my.input, mean = mean(x), median = median(x))
  [1] -0.3508165
  > my.input <- "variance"
  > switch(my.input, mean = mean(x), median = median(x))
  
  **Note**
  You can also include a single unnamed value, *i.e.* a `<\text{code }_i>` without the associated `<\text{expr: case }_i>`. This value will then be output instead of `NULL` when the value of the argument `EXPR` is not equal to any of the cases.

  ```r
  > switch(EXPR = "b", a=4, b=2:3, "Else: nothing")
  [1] 2 3
  > switch(EXPR = "QQ", a=4, b=2:3, "Else: nothing")
  [1] "Else: nothing"
  ```
• **Instructions if and else**

The conditional instruction `if` can be used in the two following ways:

```r
if (<cond>) <expr:true>
```

or

```r
if (<cond>) <expr:true> else <expr:false>
```

The argument `<cond>` must be a logical value, which therefore takes one of the values *TRUE* or *FALSE*. Note that `<cond>` is first transformed by `as.logical(<cond>)`, so that real numbers are allowed (**0** is the only number to be transformed into *FALSE*) as well as character strings "T" or "TRUE" and "F" or "FALSE". Also note that `<cond>` must be of length 1. Otherwise, only the first element of `<cond>` will be taken into account, and R will display a warning.

In practice, of course, `<cond>` is often the result of an elaborate logical operation, computed with the logical operators we described above. Here is an example of how these instructions can be used. Make sure you understand them well.

```r
> if (TRUE) 1+1
[1] 2
> x <- 2
> y <- -3
> if (x <= y) {
+   z <- y-x
+   print("x smaller than y")
+ } else {
+   z <- x-y
+   print("x larger than y")
+   z
+ }
[1] "x larger than y"
[1] 5
```

**Tip**

The function `ifelse()` is used to execute one or the other of two functions applied to a vector, depending on the values of a logical condition. For example:

```r
> x <- c(3:-2)
> sqrt(ifelse(x >= 0, x, NA))
[1] 1.732051 1.414214 1.000000 0.000000 NA NA
```

• **Preferred logical operators**

Make sure you use logical operators well. For conditional instructions, we advise you to use:

- `x && y` rather than `x & y`;
- `x || y` rather than `x | y`.
This next example shows why. If you use the long form &&, the logical conditions after the if are evaluated from left to right, until a FALSE is found.

```r
dm(x <- 2) # as.logical(x, non-zero real number)
  # outputs TRUE.

> x
[1] 2
> rm(x) # Remove x.

> if (FALSE & as.logical(x <- 2)) 4*7 # <cond> is evaluated to
  # be FALSE. Both parts
  # of <cond> are
  # evaluated.

> x
[1] 2

> if (FALSE && (x <- 3)) 4*7 # If you use &&, only the first
  # part of <cond> is evaluated.

> x
[1] 2
```

When you use the long form ||, the logical conditions after if are evaluated from left to right until a TRUE is found. You should therefore use the long form, since it will make your code run faster.

- **The function all.equal() for the if() instruction**

  When using the if() instruction, you should:
  - use `isTRUE(all.equal(x,y))` rather than `x == y`;
  - use `!isTRUE(all.equal(x,y))` rather than `x != y`.

  This point is illustrated in the following example, in which `x` and `y` are not exactly equal, because of machine precision:

```r
> x <- 0.1
> y <- 0.1
> x==y
[1] TRUE
> x <- 0.2-0.1 # It seems that
> y <- 0.3-0.2 # x is equal to y.
> x == y # This is not the case, because the computer
  # has a limited precision. See section
  # 3.9.

[1] FALSE
> all.equal(x,y,tolerance=10^-6) # The function all.equal()
  # solves this issue.

[1] TRUE
```
The function `all.equal()` takes an optional argument `tolerance`, used to fix the tolerance limit below which the difference between two values is taken to be zero.

### 3.7.2 Loop instructions

A loop is a control structure which allows a portion of code to be executed several times in a row, until an exit condition is satisfied, or until a pre-specified number of loops has been reached.

There are three loop instructions in R: `for`, `while` and `repeat`. In addition, the reserved words `next` and `break` give extra control on code execution. The instruction `break` immediately exits the current loop. The instruction `next` takes the program execution back to the beginning of the loop, so that the next iteration (if it exists) of the loop is then executed. For the current iteration, no instruction after `next` is executed.

#### Instruction for

The syntax for this instruction is as follows:

```
for (i in vect) <Instructions>
```

Here are two examples:

```r
> for (i in 1:3) print(i)
[1] 1
[1] 2
[1] 3
> x <- c(1,3,7,2)
> for (var in x) print(2*var)
[1] 2
[1] 6
[1] 14
[1] 4
```

The following list of instructions prints a decreasing counter:

```r
n<-100;
for (i in 1:n) { flush.console();cat(n-i,"\r");Sys.sleep(0.1)}
```
3.7 Control flow

• Instruction while

The syntax for this instruction is as follows:

```r
while(<condition>) <expression>
```

For example:

```r
> x <- 2
> y <- 1
> while(x+y<7) x <- x+y
> x
[1] 6
```

• Instructions next and break

```r
> for (i in 1:4) {
+   if (i == 3) break
+   for (j in 6:8) {
+     if (j==7) next
+     j <- i+j
+   }
+ }
> i
[1] 3
> j
[1] 10
```

• Instructions repeat and break

```r
> i <- 0
> repeat {
+   i<-i+1
+   if (i==4) break
+ }
```

Warning

Whenever possible, it is better to avoid loops in R, since they often slow down the execution (as measured by the function `system.time()`). Indeed, most operations in R are vectorized, which means that they can operate on vectors, and these calculations are done in a compiled language, which is much faster.

```r
> system.time(for (i in 1:1000000) sqrt(i))
user    system     elapsed
0.342 0.001      0.343
> system.time(sqrt(1:1000000))
user    system     elapsed
0.018 0.004      0.022
```
Moreover, functions such as apply(), tapply() and sapply() give a way to use loops in an implicit, and often very useful, manner.

SECTION 3.8

Creating functions

We saw in section 1.1.4, page 41, some brief notions on executing functions in R. The R language can also be used to create your own functions. We propose an overview in this section. The reader should linger on all the code given in this section, to ensure it is well understood.

See also

A more formal presentation of function writing is given in chapter 6.

To illustrate simply the function creation process, we shall focus on the computation of the Body Mass Index (BMI), from the weight (in kg) and the height (in m), using the well-known formula

\[
BMI = \frac{\text{Weight}}{\text{Height}^2}.
\]

This is easily programmed in R as follows:

```r
> BMI <- function(weight,height) {
+ bmi <- weight/height^2
+ names(bmi) <- "BMI"
+ return(bmi)
+ }
```

Warning

The function return() is optional in the code above, but you should take the habit of using it. Indeed, there are contexts where it is essential:

```r
> f <- function(x) {
+ res <- vector("numeric",length(x))
+ for (i in 1:10) {
+ res[i] <- rnorm(1) + x[i]
+ }
+ # Forgot to include return(res)
+ }
> f(1:10) # Does not output anything!
```

We can now execute the function BMI() we just created:
3.8 Creating functions

> BMI(70, 1.82)
BMI
21.13271
> BMI(1.82, 70) # Note that it is not possible to swap the
# arguments of a function,
BMI
0.0003714286
> BMI(height=1.82, weight=70) # unless they are preceded by their
# names.
BMI
21.13271

This function only outputs a single value. The code below outputs a list of several variables.

> BMI <- function(weight, height) {
+ bmi <- weight / height^2
+ res <- list(weight, height, bmi)
+ return(res)
+ }

The next instruction shows that the new function BMI() returns a list of unnamed elements.

> BMI(70, 1.82)
[[1]]
[1] 70
[[2]]
[1] 1.82
[[3]]
[1] 21.13271

Do it yourself

Write a function called biroot() which calculates the roots of a polynomial of order 2, i.e. the values x which solve the equation \( ax^2 + bx + c = 0 \). Recall that they can be complex, and are given by

\[
x = \frac{-b \pm \sqrt{\Delta}}{2a}
\]

with

\[
\Delta = b^2 - 4ac.
\]

If \( \Delta = 0 \), there is only one solution; return only that value. If \( \Delta < 0 \), then the square root of \( \Delta \) is the complex number \( z \) such that \( z^2 = \Delta \). (Hint: use the instruction as.complex(Delta)).

Compare the results of your function with those given by the function polyroot() (remember to use the online help for this function: ?polyroot).
To name the elements of the list, you can use the following code:

```r
> BMI <- function(weight, height)
+   bmi <- weight / height^2
+   res <- list(Weight = weight, Height = height, BMI = bmi)
+   return(res)
+
which gives the following result:

```r
> BMI(70, 1.82)

$Weight
[1] 70

$Height
[1] 1.82

$BMI
[1] 21.13271
```

Now assume we wish to calculate the BMI of several individuals, for example John and Peter:

```r
> John <- c(74, 1.90)
> Peter <- c(70, 1.82)
> mydata <- rbind(John, Peter)

We might use the following code:

```r
> for (i in 1:2) {
+   print(BMI(mydata[i, 1], mydata[i, 2]))
+ }

$Weight
John
74

$Height
John
1.9

$BMI
John
20.49861

$Weight
Peter
70

$Height
Peter
1.82

$BMI
Peter
21.13271
```

But the attentive reader will have noticed that many R functions (including the division, multiplication and exponentiation operators) work very well with vectors. The following output is thus not surprising:

```r
> BMI(c(70, 74), c(1.82, 1.90))

$Weight
[1] 70 74
```
The following code illustrates the use of an argument with a default value, as well as the function `stop()` which can handle some input errors.

```r
BMI <- function(weight, height, height.unit="m") {
  if (length(weight) != length(height))
    stop("The vectors weight and height must have the same length.")
  if (height.unit == "cm") height <- height/100
  bmi <- weight/height^2
  res <- list(Weight=weight, Height=height, BMI=bmi)
  return(res)
}
```

Using the function `stop()` can lead to annoyances. For example, in a simulation study, one often has to call a function repeatedly. If in one of the calls, the function returns an error, the simulation is stopped. It is advisable to use the function `try()`. If the function encounters an error, the error message is stored in an object without stopping the simulation.

```r
> set.seed(123)
> x <- rnorm(50)
> doit <- function(x) {
  x <- sample(x, replace=TRUE)
  if(length(unique(x)) > 30) mean(x)
  else stop("too few unique points")
}
> res <- lapply(1:100, function(i) try(doit(x), TRUE))
> res[8:10]
[[1]]
 [1] 0.2030573
[[2]]
 [1] "Error in doit(x) : too few unique points"
attr("class")
 [1] "try-error"
[[3]]
 [1] 0.235046
```

It is possible to classify individuals into weight categories depending on their BMI. The correspondence between BMI and categories is given in table 3.4.
Table 3.4: Correspondence between BMI and weight categories.

<table>
<thead>
<tr>
<th>severely underweight</th>
<th>underweight</th>
<th>normal weight</th>
<th>overweight</th>
<th>moderate obesity</th>
<th>severe obesity</th>
<th>morbid obesity</th>
</tr>
</thead>
<tbody>
<tr>
<td>[15; 16.5)</td>
<td>[16.5; 18.5)</td>
<td>[18.5; 25)</td>
<td>[25; 30)</td>
<td>[30; 35)</td>
<td>[35; 40)</td>
<td>[40; 41]</td>
</tr>
</tbody>
</table>

The next function outputs a user’s weight category given their BMI.

```r
> weight.category <- function(bmi)
+ if (bmi<16.5) category <- "severely underweight" else {
+ if (bmi<18.5) category <- "underweight" else {
+ if (bmi<25) category <- "normal weight" else {
+ if (bmi<30) category <- "overweight" else {
+ if (bmi<35) category <- "moderate obesity" else {
+ if (bmi<40) category <- "severe obesity" else {
+ category <- "morbid obesity"}}}}}}}
+ cat(paste("Your BMI is: ",round(bmi,3),".\n
+ This corresponds to category: ",category,".\n
+ )
```

Here is an example of use:

```r
> weight.category(BMI(70,1.82)$BMI)
Your BMI is: 21.133.
This corresponds to category: normal weight.
```

The code of the function `weight.category()` can be simplified with the function `switch()`, as can be seen below:

```r
> weight.category <- function(bmi)
+ intervals.BMI <- c(15,16.5,18.5,25,30,35,40,41)
+ code <- as.character(rank(c(bmi,intervals.BMI),
+ ties.method="max")[1])
+ category <- switch(code,"2"="severely underweight",
+ "3"="underweight","4"="normal weight","5"="overweight","6"=
+ "moderate obesity","7"="severe obesity","8"="morbid obesity")
+ cat(paste("Your BMI is: ",round(bmi,3),".\n
+ This corresponds to weight category: ",category,".\n
+ )
```

```r
> weight.category(BMI(70,1.82)$BMI)
Your BMI is: 21.133.
This corresponds to weight category: normal weight.
```

However, this function outputs wrong results when used on a vector:

```r
> weight.category(BMI(c(70,74),c(1.82,1.90))$BMI)
Your BMI is: 21.133.
This corresponds to weight category: overweight.
Your BMI is: 20.499.
This corresponds to weight category: overweight.
```

Our function can be improved so that it works on several individuals simultaneously. Note the use of the reserved word `NULL` and of the function `is.null()` which handles shrewdly the parameter names.
3.8 Creating functions

```r
> weight.category <- function(bmi, names=NULL) {
+   intervals.BMI <- c(15, 16.5, 18.5, 25, 30, 35, 40, 41)
+   n <- length(bmi)
+   if (is.null(names)) names <- paste("Subject number", 1:n)
+   if (length(names) != n) stop(paste("The vector of 'names'
+       must be of length", n))
+   code <- vector("integer", length=n)
+   category <- vector("character", length=n)
+   for (i in 1:n) {
+     code[i] <- as.character(rank(c(bmi[i], intervals.BMI),
+       ties.method="max")[1])
+     category[i] <- switch(code[i], "2"="severely underweight",
+       "3"="underweight", "4"="normal weight", "5"="overweight", "6"
+         = "moderate obesity", "7"="severe obesity", "8"="morbid obesity")
+   }
+   cat(paste(names[i], "Your BMI is: ", round(bmi[i], 3), ".
+     This corresponds to weight category: ", category[i], ".", sep=""))
+ }
>
Here is an example of use.

> weight.category(BMI(c(70, 74), c(1.82, 1.90))$BMI)
Subject number 1:
Your BMI is: 21.133.
This corresponds to weight category: normal weight.
Subject number 2:
Your BMI is: 20.499.
This corresponds to weight category: normal weight.

Tip

In the previous function, we declared, directly with the correct length, the vectors `code` and `corpulence` thanks to the function `vector()`. However, it is also possible to handle a vector without a predefined dimension (ever because we do not know its length initially, or for another reason). This is illustrated on the next example, where we compute the first terms of the Fibonacci sequence, which is defined by:

\[ a_1 = 0, a_2 = 1, a_i = a_{i-1} + a_{i-2}, \forall i \geq 3. \]

```r
> a <- c(0, 1)
> for(i in 3:10) a <- c(a, a[i-1]+a[i-2])
> a
[1] 0 1 1 2 3 5 8 13 21 34
```

We could also use the function `while()` to display all the terms of the Fibonacci sequence until the first term greater than 1000.

```r
> a <- c(0,1)
> i <- 3
> while(a[i-1]<1000) {
+   a <- c(a, a[i-1]+a[i-2])
+   i <- i+1
```
We could also have used the instruction `break` for a slightly different function.

```r
> a <- c(0, 1)
> i <- 3
> while(TRUE) {
+   a <- c(a, a[i-1] + a[i-2])
+   if (a[i] > 1000) break; # Stops the loop.
+   i <- i+1
+ }
> a
[1] 0 1 1 2 3 5 8 13 21 34 55
[12] 89 144 233 377 610 987 1597
```

`Warning`

The programming method presented in the previous hint is not necessarily optimal in terms of memory allocation, as we shall see in chapter 6.

---

**SECTION 3.9**

† Fixed-point and floating point number representation

This (rather technical) note aims to help the R user to identify and prevent some mistakes due to use of so-called floating point numbers.

### 3.9.1 Representing a number in a base

Given a base $b$ (integer value, greater than or equal to 2), any real number $x \in \mathbb{R}$ can be written in fixed-point representation as follows:

$$x = \sum_{i=-\infty}^{\infty} m_i b^i,$$
where the coefficients $m_i$ (also called the digits) belong to the set $\{0, 1, \ldots, b - 1\}$, $\forall i \in \mathbb{Z}$.

For example, the number $x = 10.625$ can be written in decimal notation ($b = 10$) as:

$$x = 1 \times 10^1 + 0 \times 10^0 + 6 \times 10^{-1} + 2 \times 10^{-2} + 5 \times 10^{-3},$$

hence the notation **10.625** which gives the coefficients of the representation (or digits). By noting that $10.625 = 8 + 2 + 0.5 + 0.125$, this same number can be written in binary notation ($b = 2$; hence the only digits are 0 and 1) as:

$$x = 1 \times 2^3 + 0 \times 2^2 + 1 \times 2^1 + 0 \times 2^0 + 1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3}.$$ We thus have the representation of the number 10.625 in binary form **1010.101**, which makes explicit the coefficients of the binary representation.

**Tip**

The package associated with this book includes the functions `dec2bin()` and `bin2dec()` which can be used to switch from decimal to binary representation, and vice-versa.

```r
> bin2dec(1010.101)
[1] 10.625
> dec2bin(10.625,3)
[1] "1010.101"
```

**Note**

A number with finite base 10 expansion (finite number of digits after the decimal separator) is called a **decimal number**. A number with finite base 2 expansion is called a **dyadic number**. Obviously, some numbers are neither decimal nor dyadic. Note that a dyadic number is always also a decimal number, but the converse is false. Thus a loss of information is always possible when switching from one representation to another. Furthermore, dyadic decimal fractions have the same number of digits as their binary equivalents whereas non-dyadic decimal values have infinite binary equivalents.

A computer is a machine built to work with binary numbers, because the two digits 0 and 1 are easily translated as the presence or absence of an electric current. Because fixed-point representations are often very costly in **bits** (a bit is a binary digit, *i.e.* 0 or 1), computers generally use floating point representations. These are described in the next subsection.
3.9.2 Floating point representations

3.9.2.1 Definitions

Given a base $b$ (ex: $b = 2$ for the binary system or $b = 10$ for the decimal system, to cite only the two most classical systems), any real number $x \in \mathbb{R}$, can be written as:

$$x = (-1)^s mb^e$$

where

- $s$ is called the sign bit (of $x$), and is worth 0 or 1;
- $m$ is the significand or mantissa and can be written $m = m_1.m_2m_3 \cdots m_\infty$ where each $m_i \in [0, 1, \ldots, b - 1]$ is called a digit;
- $e \in \mathbb{Z}$ is called the exponent.

This notation is called the floating point representation of $x$ in base $b$. The integer $m_1$ is the integer part of the significand, the other digits $m_2 \cdots m_\infty$ are the fractional part of the significand. Note that we must impose a constraint, that the first digit be non-zero ($m_1 \neq 0$), so as to insure that the representation is unique. Of course, this constraint cannot be applied for the particular case $x = 0$.

Let us give a first example. In the decimal system, the number $-0.6345$ can be written in floating point representation by taking $s = 1$, $m_1 = 6$, $m_2 = 3$, $m_3 = 4$, $m_4 = 5$, $m_i = 0$, $\forall i > 4$, $b = 10$ and $e = -1$:

$$-0.6345 = (-1)^16.345 \times 10^{-1}.$$  

Actually, in a computer, any real number $x$ is represented in a binary base, with bits (0 or 1), using the slightly different formula:

$$x = (-1)^s(1+f)2^{(e-1023)} \quad (3.1)$$

where $s$ is an integer coded on a single bit (called sign bit), $e$ is a non-negative integer coded on 11 bits (thus taking the values from 0 to $2^{11} - 1 = 2047$), and $f \in [0; 1)$ is a number coded on 52 bits, thus written

$$f = \sum_{i=1}^{i=52} k_i2^{-i}. \quad (3.2)$$
where the $k_i$’s take the values 0 or 1. By convention, the value $e = 0$ means that $x = 0$, and the value $e = 2047$ means that $x = +\infty$ or $x = -\infty$, depending on the value on $s$. The following two examples illustrate this:

```r
> s <- 1; e <- 2047; f <- 0; x <- (-1)^s * 2^(e-1023) * (1+f); x
[1] -Inf
> s <- 0; e <- 2047; f <- 0; x <- (-1)^s * 2^(e-1023) * (1+f); x
[1] Inf
```

### 3.9.2.2 Limitations of this representation due to the significand

The vast majority of modern computers use the floating point representation. However, it is essential to note that because of physical limitations, this representation is not perfect. Indeed, the significand $m$ can only have a limited (finite) number of digits, and the relative integer $e$ is bounded, $e \in [e_{\text{min}}, e_{\text{max}}]$, since it is not possible to code an infinite number of integers on a physical machine made of a finite number of components.

Here is a simple example, which should help understand this limitation. The floating point representation in base 10 of the real number $1/3$ is written:

$$
1/3 = (-1)^0 \times 3.3333 \ldots \times 10^{-1}.
$$

It is of course not possible to store an infinite number of 3s on a computer. A more striking example is the number $\pi = 3.14159265358979 \ldots$ for which there is no pattern in the digits after the decimal point. But it is also true for numbers which appear simpler, such as 0.1 or 0.9 for example.

This is illustrated in the output below, for the number 0.9, which can be written in floating point representation as $0.9 = (-1)^0 \times 2^{-1} \times (1+f)$ with $f = 0.8$. However, since $f$ is coded on “only” 52 bits (see (3.2)), the computer only keeps an approximation. The display function `formatC()` gives an idea of the value used by R.

```r
> dec2bin(0.8,52)
[1] "0.1100110011001100110011001100110011001100110011001101"
> f <- 2^(-1)+2^(-2)+2^(-5)+2^(-6)+2^(-9)+2^(-10)+2^(-13)+
+ 2^(-14)+2^(-17)+2^(-18)+2^(-21)+2^(-22)+2^(-25)+2^(-26)+
+ 2^(-29)+2^(-33)+2^(-34)+2^(-37)+2^(-38)+2^(-41)+
+ 2^(-42)+2^(-45)+2^(-46)+2^(-49)+2^(-50)+2^(-52)
> f # Careful: the display is in fact truncated.
[1] 0.8
> formatC(f,50) # Fractional part of the closest significand to
# 0.8 that the computer can get on 52 bits.
[1] "0.80000000000000004440892098500626161694526672363281"
> formatC(0.8,50)
[1] "0.80000000000000004440892098500626161694526672363281"
```
We can now display the value stored and used by the computer instead of the value 0.9:

```r
> formatC(0.9,50)
[1] "0.9000000000000000222044604925031308084726336181641"
> formatC((-1)^0 * 2^-1 * (1+f),50)
[1] "0.9000000000000000222044604925031308084726336181641"
> formatC((-1)^0 * 2^-1 * (1+0.8),50)
[1] "0.9000000000000000222044604925031308084726336181641"
```

### 3.9.2.3 Avoiding some numerical pitfalls

First, we shed light on a numerical oddity.

```r
> identical(1.0-0.9,0.1)
[1] FALSE
> (1.0-0.9) == 0.1
[1] FALSE
```

We can now understand this output. Indeed, the numbers 1.0 − 0.9 and 0.1 are represented in different ways, because even though 1 is perfectly represented, 0.1 and 0.9 are not.

```r
> formatC(1.0,50)
[1] " 1"
> formatC(0.9,50)
[1] "0.9000000000000000222044604925031308084726336181641"
> formatC(1.0-0.9,50)
[1] "0.099999999999999977795539507496869191527366638183594"
> formatC(0.1,50)
[1] "0.1000000000000000055511151231257827021181583404541"
```

and we thus have:

```r
> formatC(1.0 -
+ 0.9000000000000000222044604925031308084726336181641,50)
[1] "0.099999999999999977795539507496869191527366638183594"
> # which is different from:
> formatC(0.1,50)
[1] "0.1000000000000000055511151231257827021181583404541"
```

**Tip**

It is better to use the function `all.equal()` to compare two numbers, because it includes a numerical tolerance argument.

```r
> all.equal(1.0-0.9,0.1,tol=10^-6)
[1] TRUE
```
3.9† Fixed-point and floating point number representation

Warning
Do not use constructions such as `while(x != 0)` or `if (x != 0)`. Indeed, if `x` happens to take a value such as `1.0 - 0.9 - 0.1` when your code runs, those two instructions will not behave as expected. You should use instead `isTRUE(all.equal(x,0))` and `isTRUE(all.equal(x,0)).`

We leave it to the reader to understand the output below.

```r
> as.integer(100*(1-.34))
[1] 65
> floor(100*(1-.34))
[1] 65
> round(100*(1-.34))
[1] 66
> 100*(1-.34)-66
[1] -1.421085e-14
> floor(100*(1-.38))
[1] 62
> round(100*(1-.38))
[1] 62
> 100*(1-.38)-62
[1] 0
```

See also
You may find [7] useful in this context.

3.9.2.4 Limitations of this representation due to the exponent

- Smallest and largest numbers which can be represented.

Another problem due to the floating point notation is as follows. Since the exponent `e` of the representation

\[ x = (-1)^s(1 + f)2^{(e-1023)} \]  

is necessarily bounded (since it is coded on 11 bits), there exist a smallest and largest real number which can be represented on a given computer. Trying to represent a number out of this range will lead to an underflow or overflow. R is rather well conceived and will return the value `-Inf` or `+Inf`. The following R commands illustrate this point.

```r
> .Machine$double.xmin # Smallest real number which can be coded:
[1] 2.225074e-308
> # which can also be found by:
> s <- 0; e <- 0; f <- sum(2^(-(1:52)))
> x <- (-1)^s * 2^(e-1023) * (1+f); x
```
Data manipulation, functions

1. \[2.225074 \times 10^{-308}\]

\texttt{>.Machine$double.xmax} # Largest real number which can be coded:

\[1.797693 \times 10^{308}\]

# which can also be found by:

\texttt{s <- 0; e <- 2046; f <- sum(2^{-(1:52)})}

\texttt{x <- (-1)^s * 2^{(e-1023)} * (1+f); x}

\[1.797693 \times 10^{308}\]

Tip

The package \texttt{Brobdingnag} allows handling much larger numbers.

- Gaps between two numbers.

One last warning may be useful: it is important to note that it is not possible to get some numbers between \texttt{.Machine$double.xmin} and \texttt{.Machine$double.xmax} (even integers).

For example, take the number \(2^{150}\), which is represented as:

\((-1)^0(1 + 0)2^{1173-1023}.

The next number that the computer can code is given by the values \(s = 0, e = 1173\) and \(f = 2^{-52}\) (smallest non-zero fractional part of the significand), \textit{i.e.}:

\((-1)^0(1 + 2^{-52})2^{150} = 2^{150} + 2^{150-52} = 2^{150} + 2^{98}.

There can thus be a huge “gap” (of length \(2^{98} \approx 3.2 \times 10^{29}\) here) between two “successive” numbers!

This explains the following oddity:

\texttt{a <- 2^{150}; b <- a + 2^{97}; b == a}

\[1. \text{TRUE}\]

\texttt{a <- 2^{150}; b <- a + 2^{98}; b == a}

\[1. \text{FALSE}\]

Tip

More information on the computer’s limitations in representing numbers are given by the instruction \texttt{.Machine}:

\texttt{noquote(unlist(format(.Machine)))}

\begin{verbatim}
  double.eps  double.neg.eps 2.220446e-16 1.110223e-16
double.xmin  double.xmax 2.225074e-308 1.797693e+308
double.base  double.digits 2 53
double.rounding  double.guard
\end{verbatim}

Memorandum

length(): length of a vector
sort(): sort the elements of a vector
rev(): rearrange the elements of a vector in reverse order
order(): return the vector of order ranks of the elements of its effective argument
unique(): remove the duplicates from a vector
dim(): size of a matrix or data.frame
nrow(), ncol(): number of rows, columns
dimnames(): names of rows and columns
rownames(), colnames(): names of rows, of columns
rbind(), cbind(): merge rows, columns of a matrix
merge(): smart merge of columns
apply(): apply a function to the rows or columns of a matrix
lapply(), sapply(): apply a function to the elements of a list
<, <=, >, >=, ==, !=: comparison logical operators
!, & & | ||: term-wise logical operators
any(x): return TRUE if one of the \(x_i\) is true
all(x): return TRUE if all the \(x_i\) are true
if, else, switch: conditional instructions
for, while, repeat: loop instructions
"["(): extraction operator for vectors and matrices
"[["(): extraction operator for lists
which(): indices of the values TRUE of a logical object
nchar(): number of characters in a string
paste(): concatenate two strings
substring(): extract sub-strings
strsplit(): split strings
grep(): search for a pattern in a string
sub(), gsub(): replace occurrences of a pattern in a string
Sys.time(): display the date
strptime(): extract dates from a string
as.POSIXlt(): convert to the POSIXlt format
difftime(): calculate the difference between two dates

Exercises

3.1- What is the output of this instruction: \(c(1,4)^*c(2,3)\)?
3.2- What is the output of this instruction: \(\text{matrix}(1:2,\text{nrow}=2,\text{nrow})\)?
3.3- How can you retrieve the names of rows and columns of a data.frame?
3.4- Give the instruction to merge these two tables:

```r
> X
  Gender Weight
  Jack   M   80
  Julia  F   60
> Y
  Eyes Height
```
3.9 - Fixed-point and floating point number representation

3.5 - Give the instruction to calculate the product of all the elements (respectively: of all the elements of each column) of a numerical matrix X.

3.6 - What is the output of this instruction: vec<-c(2, 4, 6, 8, 3); vec[2]; vec[-2]?

3.7 - The height and weight of several men were measured. The measurements are stored in the vectors weight and height. Give the R instruction to get the weight of the men whose height is greater than 180 cm.

3.8 - What is the output of this instruction
Mat<-matrix(1:12,nrow=4,byrow=TRUE); Mat[3,]; Mat[2,2:3]?

3.9 - How could you replace the fourth component of the following list with 1:10?
L<-list(12,c(34,67),Mat,1:15,list(10,11))

3.10 - What is the output of this instruction: L[[2]][2]?

3.11 - Give the R instruction which outputs the weights and heights of all women in the following table (you can use the function attach()):

```
> X
   weight height gender
1 79     163    M
2 90     163    F
3 87     198    M
4 63     164    F
5 90     168    F
6 71     178    F
7 58     191    M
8 80     194    F
9 91     185    F
10 89     176   M
```

3.12 - What is the output of this instruction: (1:3)[any(c(T,F,T))]? And this one: (1:3)[all(c(T,F,T))]

3.13 - What is the output of this instruction: c(T,T,F) | c(F,T,F)? And this one: c(T,T,F) || c(F,T,F)?

3.14 - What is the output of this instruction: nchar(c("abcd","efgh"))?

3.15 - What is the output of this instruction:
```
paste(c("a","b"),c("c","d"),collapse="",sep="")
```

3.16 - What is the output of this instruction: strsplit(c("ab;cd"),";")?

3.17 - What is the output of this instruction: substring("abcdef",3,c(2,4))?

3.18 - How could you transform the upper case into lower case in the following vector?
c(“Jack”,”Julia”,”William”)

3.19 - Which function is used to retrieve a date from a character string?

3.20 - Can you explain why the second number of the last output is not equal to 36.21313?

```R
> logp <- function(x) log(max(x,exp(1)))
> x <- -2.4
> delta <- 0.1
> (abs(x))^4+delta/(logp(abs(x)))^2
```
Propose a solution to this problem.

Worksheet

Manipulating various data sets

A- Manipulating a few data sets presented at the beginning of the book

These files can be downloaded from the URL http://www.biostatisticien.eu/springeR/. Note that you can also append the file name at the end of this URL to download the file directly from R (e.g. http://www.biostatisticien.eu/springeR/nutrien1.xls).

Data set NUTRIELDERLY:

The data file nutrition\_elderly.xls, described earlier in this book, is in fact the merge of two initial files, entered by different operators. We propose to reconstruct the file for the following cases. You will only use R, and will not edit the file by hand.

3.1- The individuals are initially listed separately in two files (nutrien1.xls and nutrien2.xls). Note that the variable names are in upper case in the first file, and in lower case in the second.

3.2- Some individuals are listed in both files (nutrien3.xls and nutrien4.xls). The variable names are identical.

3.3- Same question as 3.2, but errors have slipped in and you will need to detect the corresponding individuals, for example those with a weight greater than 200 kg (nutrien5.xls and nutrien6.xls).

3.4- The variables are split between two files (nutrien7.xls and nutrien8.xls), which contain the same individuals.

3.5- Same question as 3.4, but for one variable, too many values are missing. Remove that variable (nutrien9.xls and nutrien10.xls).

3.6- Same question as 3.4, but for one individual, too many values are missing. Remove that individual (nutrien11.xls and nutrien12.xls).

3.7- In the file nutrition\_elderly.xls, how many people are vegetarians (no meat, no fish)?
3.9 Fixed-point and floating point number representation

File Intima_Media_Thickness.xls:

3.1- Add a column BMI to the data.frame, with the BMI of each individual in the data file.
3.2- Retrieve the thickness of intima for the people with a BMI > 30.
3.3- Extract the “athletic” women.
3.4- Extract the “non-obese” people aged 50 or other (obese = BMI > 30).

File bmichild.xls:

3.1- Add a column BMI.
3.2- Extract the children with a BMI < 15 and an age <= 3.5 years.
3.3- How many such children are there?

File Birth_weight.xls:

3.1- Add a variable PTL1 (number of children born before term), with three modalities (where the third modality, coded 2, corresponds to “2 or more” pre-term births).
3.2- Same question with FVT (number of visits to a physician), to add FVT1.
3.3- Sort the file by increasing weight at birth (BWT).
3.4- Extract the individuals whose mothers are black or white and smoke.

B- Handling missing values

Import into a data.frame the following file:

http://www.biostatisticien.eu/springeR/Infarction.xls

3.1- Which rows include missing values?
3.2- Which individuals have more than one missing value?
3.3- Which variables include missing values?
3.4- Give at least one solution to remove all rows of this data.frame which include at least one missing value. In addition to logical operators and the extracting function, you are only allowed to use:
   a) the functions is.na(), prod(), apply() and as.logical();
   b) the functions is.na(), apply() and any();
   c) the functions is.na(), apply() and all();
   d) the function complete.cases();
   e) the function na.omit().
C- Handling character strings

3.1- Import the file `www.biostatisticien.eu/springeR/dept-pop.csv` into a data.frame called `dept`.
3.2- Replace the first column with two new columns: one called `numdep` with the French départements numbers, and another with the names.

D- Influenza epidemics in France since 1984

3.1- Import the file `http://www.biostatisticien.eu/springeR/flu.csv` into a data.frame called `flu`. Make sure that you are handling missing values correctly.
3.2- Type `names(flu)` As you can see, `flu$Date` includes dates in the format year (with century; for example: 2003) followed by the week number (two digits).
3.3- Determine the list of possible week numbers (hint: use the functions `sort()`, `substring()` and `unique()`).
3.4- First, you need to retrieve these dates in R in an object of class `POSIXlt`, for example with the function `strptime()`. Using Table 3.3, and this function, transform the first (oldest) date into the POSIX format.
3.5- The data are in fact updated every Monday, since the first week. Determine which is the oldest date (Day, Month, Year) for which observations exist (hint: use the calendar `http://sentiweb.fr/calendrier.php`).
3.6- You should notice that there is a difference with the answer to question 3.4. To solve this problem, try adding a “1” at the end of the first date, and transforming it again with the function `strptime()`.
3.7- Display the ten first dates from the data files. Use the hint from the previous question to transform them with the function `strptime()`. Is the last date correct? If not, do you have an idea to solve this problem?
3.8- At this point, you should realize that the format of the dates in this file is not compatible with the POSIX format (which takes week numbers between 00 and 53). It is therefore not possible to directly use the function `strptime()` or `as.POSIXlt()` to transform these dates into an object type easy to handle by R. Type in the instruction:
   ```r
date1 <- as.POSIXlt("Day, Month, Year", format="to be specified")
```
   where you will replace `Day`, `Month` and `Year` with the oldest date, and `to be specified` with the relevant date format.
3.9- Type in the instruction `date1` then `date1+7`. What do you notice?
3.10- Find a way to add seven days to `date1` (hint: how many seconds are there in a day?).
3.11- Now, create the vector `dates` containing all the dates in the POSIX format, sorted from most ancient to newest (hint: use the function `nrow()`).

---

1 Source: `http://www.sentiweb.fr/?lang=en`
3.12- Use the function `substring()` on the vector `dates` to replace the first column of the data.frame `flu` with dates in the format "year-month-day" (for example: "1992-12-07").

3.13- Use the vector `dates` and what you have learnt about extraction to select only the portion of the data.frame `flu` for dates between 15 September 1992 and 3 November 1993. Store this sub-table in an object called `portion`.

3.14- Calculate the number of cases of influenza over this period for each French region (hint: pay attention to missing values; use the argument `na.rm`). Store the results in a vector called `flucases`.

E- Combining tables or lists; other manipulations

3.1- Input into R the two following tables (check the row names).

```r
> a
[,1] [,2]  
1  1  4  
2  2  5  
6  3  6
> b
[,1] [,2]  
3  1  5  
4  2  6  
5  3  7  
7  4  8
```

3.2- Combine `a` and `b` into a new table called `ab` containing:

```r
> ab
[,1] [,2]  
1  1  4  
2  2  5  
3  1  5  
4  2  6  
5  3  7  
6  3  6  
7  4  8
```

(hint: use `rbind()` and `order()`).

3.3- Concatenate the elements of `list1` as columns of one matrix:

```r
> list1 <- list()
> list1[[1]] <- matrix(runif(25), nr=5)
> list1[[2]] <- matrix(runif(30), nr=5)
> list1[[3]] <- matrix(runif(15), nr=5)
```

(hint: use the function `unlist()` or the function `do.call()`).

3.4- Concatenate the elements of `list2` as rows of one matrix:
> list2 <- list()
> list2[[1]] <- matrix(runif(25),nc=5)
> list2[[2]] <- matrix(runif(35),nc=5)
> list2[[3]] <- matrix(runif(15),nc=5)

(hint: use the function `unlist()` or the function `do.call()`).

3.5- Automatically select the diseases which have tobacco as a risk factor.

> tmp

<table>
<thead>
<tr>
<th>Disease</th>
<th>RiskFactors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Infarction</td>
<td>tobacco, alcohol</td>
</tr>
<tr>
<td>Hepatitis</td>
<td>alcohol</td>
</tr>
<tr>
<td>Lung cancer</td>
<td>tobacco</td>
</tr>
</tbody>
</table>

(hint: use the function `grep()`).

Creating functions

**F- The French chevalier de Méré**

The French chevalier de Méré was a keen gambler. He was particularly fond of two gambles. In the first one, he would frow a die four times and bet that a 6 would come out at least once. In the second one, he would throw two dice 24 times and bet that a double-6 would come out. He had noticed that the first gamble is “beneficial”: there is more than a 50% chance that a 6 will come out at least once. He thought that the second gamble is also beneficial.

- Propose code for a function called `fourthrows()` which returns 1 if there is at least one 6 out of 4 throws of a die, and 0 otherwise. Do not use any loops.
- Propose code for a function called `twentyfourthrows()` which returns 1 if there is at least one double-6 out of 24 throws of two dice, and 0 otherwise. Do not use loops.
- Propose code for a function called `meresix()` to confirm the chevalier de Méré’s intuition. It should use the first two functions and take a formal parameter `nsim` which gives the number of repetitions of the gamble.

Hint: use function `sample()`.
Prerequisites and goals of this chapter

- Chapter 1.
- This chapter presents the various ways to get help on the R software.

SECTION 4.1

Integrated help

4.1.1 The command help()

R includes an online help. It is very complete and very well structured for all functions and for the various symbols in the language. There are several ways to access the help files; the main method is help(). It is used in command line mode.

For example, type:

```
help(help)
```

There is an alias for the command help(): the question mark ?.

```
?sum
?sd
?"a"
?"["
Warning

Sometimes, this alias will not work. In those cases, you will need to use the function `help()` with quotation marks.

```
?function       # Does not work.
help(function)  # Returns an error.
help("function") # Correct call.
```

Let us look at the help of the function `mean()`.

```
?mean

1 mean       package:base R Documentation
2 Arithmetic Mean
3 Description:
   Generic function for the (trimmed) arithmetic mean.
4 Usage:
   mean(x, ...)
      ## Default S3 method:
      mean(x, trim = 0, na.rm = FALSE, ...)
6 Arguments:
   x: An R object. Currently there are methods for
      numeric dataframes, numeric vectors and dates.
      A complex vector is allowed for 'trim = 0', only.
   trim: the fraction (0 to 0.5) of observations to be trim-
      med from each end of 'x' before the mean is computed.
   na.rm: a logical value indicating whether ‘NA’ values
      should be stripped before the computation proceeds.
      ...: further arguments passed to or from other methods.
8 Value:
   For a data frame, a named vector with the appropriate
   method being applied column by column.
   If 'trim' is zero (the default), the arithmetic mean of
   the values in 'x' is computed.
   If 'trim' is non-zero, a symmetrically trimmed mean is
   computed with a fraction of 'trim' observations deleted
   from each end before the mean is computed.
10 References:
12 See Also:
   'weighted.mean', 'mean.POSIXct'
14 Examples:
   x <- c(0:10, 50)
   xm <- mean(x)
   c(xm, mean(x, trim = 0.10))
   mean(USArrests, trim = 0.2)
```
Here are the sections of this help file:

1. The header of the file, with:
   - the name of the function: mean;
   - the name of the package in which the function is included: base;
   - the origin of the help file: R Documentation.
2. An explicit title for the function: Arithmetic Mean.
3. A brief description of what the function does: Description.
4. How to use the function; in particular, the compulsory and optional arguments: Usage.
5. A description of the function’s arguments: Arguments.
7. References (statistical articles or books) related to the function’s application domain: References.
8. The See Also section, which lists similar or related functions.

### Warning

Most help files follow this format. Make sure you understand and remember the structure of help files. You should also take the habit of checking the online help whenever you meet an unknown function, so as to understand its arguments and use.

### Tip

Note that help files do not include graphs, for example those that could be produced with the code in the section Examples. This would be interesting, especially for all the graphical functions. One way to get them is the function example(). You can also browse the website R Graphical Manual: http://bm2.genes.nig.ac.jp/RGM2/index.php which includes all R help files in HTML. In those files, when there are graphs, they are directly included in the section Examples.

### 4.1.2 Some complementary commands

In addition to the main command, help(), a few other complementary functions can be useful when looking for help on a given command. They are listed here:

- help.start(): this function opens a web browser with links to handbooks in HTML, help on functions included in all R packages (also HTML), a FAQ
(Frequently Asked Questions), and a search engine of the help files. There are also other, more technical documents.

**Linux**

Under Linux, once you have entered the command `help.start()`, using the command `help()` will always result in the help being displayed in the web browser, rather than in the command line. To cancel this behaviour, use the instruction `options(htmlhelp = FALSE)`. To change browser (for example `firefox`), use the instruction `options(browser="firefox")`.

- `help.search()` or `??()`: this function is useful when you do not know the name of a command. It returns a list of functions (and the package in which they are included) related to your request. Try: `help.search("mean")`.

- `apropos()`: this instruction returns the names of functions which are a (potentially partial) match to the calling argument. For instance, `apropos("mean")` returns the names of functions containing the word `mean`.

**Advanced users**

Note also that the function `methods()` returns all the methods (functions) associated with an object. For instance, try `methods(summary)`.

- `library(help=package)`: this command lists all functions included in a package. It gives the same results as the command `help(package="package")`. We advise you to try the following instructions, to list the main functions in R:
  ```
  library(help=base)
  library(help=utils)
  library(help=datasets)
  library(help=stats)
  library(help=graphics)
  library(help=grDevices)
  ```

**Tip**

The function `library(lib.loc = .Library)` returns the list of all packages (or libraries) installed on the system.

Conversely, the instruction `find("function")` indicates in which package a function is included.
4.2 Help on the Web

vignette(): vignettes are small PDF files which explain some notions in further detail. Type vignette() to get a list of vignettes, and for example vignette("xtableGallery") to open the PDF vignette of the package xtable.

All vignettes can also be read in a special vignette browser, from the menu "Help/Vignettes". In this browser, you can open PDF files as well as R source code (as .R files), and consult directly the code of examples included in the vignette.

These three other functions might also be useful:

- data(): this command lists all datasets included in R.
- example(): this instruction lists examples of use of a function. For example, example(mean) executes the instructions included in the section Examples of the help file help(mean).
- demo(): this instruction is similar to example(), but is only available for a small number of functions. When it is available, it shows the range of possible uses of a function. For example, try demo(graphics).

4.2.1 Search engines

There are two main search engines for R:

- http://search.r-project.org/nmz.html
Tip

The command `RSiteSearch()` can be used to send a request on this website directly from R. The information is then displayed in your browser.

- [http://www.rseek.org/](http://www.rseek.org/)

There is also an R function finder available at the URL [http://biostat.mc.vanderbilt.edu/s/finder/finder.html](http://biostat.mc.vanderbilt.edu/s/finder/finder.html)

### 4.2.2 Message boards

There are many message boards about R, where you can ask your questions. One message board with a lot of traffic is: [http://r.789695.n4.nabble.com/](http://r.789695.n4.nabble.com/).

### 4.2.3 Mailing lists

A mailing list is a specific kind of e-mail, which sends messages to a large number of subscribers.

There are several mailing lists about R. The main ones are:

- [https://stat.ethz.ch/mailman/listinfo/r-help](https://stat.ethz.ch/mailman/listinfo/r-help)
- [http://blog.gmane.org/gmane.comp.lang.r.general](http://blog.gmane.org/gmane.comp.lang.r.general)
- [http://www.r-project.org/mail.html](http://www.r-project.org/mail.html)
- R-announce: [https://stat.ethz.ch/mailman/listinfo/r-announce](https://stat.ethz.ch/mailman/listinfo/r-announce)

The website [http://r-project.markmail.org](http://r-project.markmail.org) can be used to search the archives of these lists.

You need to follow a few rules to post a message on these lists, as described here: [http://www.r-project.org/posting-guide.html](http://www.r-project.org/posting-guide.html).

Mac

4.2.4 Internet Relay Chat (IRC)

IRC (Internet relay chat) is a real-time messaging service. You can use it to chat with other Internet users on pre-defined themes. The IRC channel on the R software is called (#R), on the freenode server.

To access it, you can either use client-side software such as xchat (www.xchat.org), or use your browser, through websites such as http://java.freenode.net/.

To connect to this channel using xchat, type in these instructions:
/server irc.freenode.net
/join #R

4.2.5 Wiki

A wiki is a website where pages can be freely edited by visitors. Wikis are used to aid collaborative writing with minimal constraints.

There is a wiki about R here: http://wiki.r-project.org/.

4.3.1 Online

Literature about R is available online in many forms:

- **Task Views**: lists of packages useful in a given domain, grouped by themes. A website describing Task Views is available at the URL http://cran.r-project.org/web/views/.

- **Frequently Asked Questions (FAQ)**: Frequently Asked Questions about R are listed here: http://cran.r-project.org/faqs.html

- **Specialized journals**: two online journals deal with the R software: the R Journal, previously known as R News (http://journal.r-project.org), and the Journal of Statistical Software (http://www.jstatsoft.org).
• **Handbooks:** many handbooks are available as a PDF on the R website. The one you are holding will soon be there: [http://cran.r-project.org/other-docs.html](http://cran.r-project.org/other-docs.html)

### 4.3.2 Printed material

Many books have been published about R recently. We find the following to be the most interesting.

- **Data Analysis and Graphics Using R: An Example-based Approach** [26]
- **The R Book** [12]
- **Statistics and Data with R** [10]
- **Software for Data Analysis: Programming with R** [8]
- **Lattice: Multivariate Data Visualization with R** [36]
- **R for SAS and SPSS users** [32]
- **Introductory Statistics with R: An Applied Approach Through Examples** [13]
- **A First Course in Statistical Programming with R** [6]
- **A Handbook of Statistical Analyses Using R** [15]
- **A Beginner’s Guide to R** [42]
- **R Cookbook** [39]
- **R in a Nutshell** [1]
- **The Art of R Programming** [28]
- **The R Inferno** [7]
Memorandum

help(), ?(): get help on a function or a symbol
help.search(): list of functions relevant to your request
apropos(): list of function names which include the request
library(help=package): list of all functions in a package
data(): list of all datasets available in R
example(): execute the Examples section of the corresponding help file
demo(): launch a small demonstration of the possible uses of a function
vignette(): open a PDF file with details on a function
help.start(): open the HTML version of the R help files
RSiteSearch(): start a request on the official R website search engine

Exercises

4.1- Which R instruction should you type to get help on the function mean()?
4.2- Explain the purpose of the command apropos().
4.3- Explain the purpose of the command example().
4.4- Explain the purpose of the command RSiteSearch().
4.5- How is a help file structured?
4.6- Which command would you use to get the list of functions available in the package stats?
4.7- Explain how to display a dataset available in R.

Worksheet

Where to find information

4.1- Find the R function which lists all combinations of \( k \) elements out of \( n \).
4.2- Use this function to list all combinations of three elements out of \( c(5, 8, 2, 9) \).
4.3- Find the dataset available in R which gives the rates of violent crimes in the USA.
4.4- Describe the contents of this dataset.
4.5- Subscribe to the mailing list https://stat.ethz.ch/mailman/listinfo/r-help.
4.6- Read the rules to follow before asking a question (http://www.r-project.org/posting-guide.html).
4.7- Find out how to unsubscribe from the mailing list.
4.8- Using the method of your choosing, join the IRC channel R and start a polite conversation with channel members.
4.9- Register on the message board http://r.789695.n4.nabble.com/.

4.10- Read the R FAQ for Windows. Try to understand the meaning of TAB completion.

4.11- Use TAB completion to list all files in the current directory.
Chapter 5
Drawing curves and plots

Prerequisites and goals of this chapter

- Reading previous chapters.
- This chapter describes the graphical possibilities of R, but does not go as far as expert graphical functions such as `hist()`, `barplot()`, and so on. These functions are described in Chapter 9. We show generic ways to make adjustments to most plots you can draw. Note that the excellent website http://addictedtor.free.fr/graphiques/ gives a broad overview of the graphical possibilities in R.

SECTION 5.1

Graphics windows

5.1.1 Basic graphics windows; manipulation; saving

All plots created in R are displayed in special windows, separate from the console. They are called “R graphics: Device device-number”, where `device-number` is an integer giving the number of the window (or device).

To open a graphics window, use the command `windows()` or `win.graph()`.

This command takes several arguments. Some are briefly described in the following table:
Width of the graphics window, in inches.
Height of the graphics window, in inches.
Default font size.
Double: Pixels per inch, horizontally and vertically.
Integer: Position of the upper left corner of the window, in pixels.

Under Linux, the command is `X11()` instead of `windows()`.

On a Macintosh, the command is `quartz()`.

When several graphics windows are open, only one is “active”. This is the window in which all graphical events occur. Each window is associated with a device number; the console is number 1.

Here are a few functions to manipulate graphics windows, using their device number.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dev.off(device-number)</td>
<td>Close window device-number (if no device number is specified, the current active window is closed).</td>
</tr>
<tr>
<td>graphics.off()</td>
<td>Close all open graphics windows.</td>
</tr>
<tr>
<td>dev.list()</td>
<td>Return the device numbers of open graphics windows.</td>
</tr>
<tr>
<td>dev.set(device-number)</td>
<td>Activate window device-number.</td>
</tr>
<tr>
<td>dev.cur()</td>
<td>Return the device number of the active window (1 for the console).</td>
</tr>
</tbody>
</table>

Note that once a plot has been drawn, it can be saved to a file with the command `savePlot()`, as follows:

```r
savePlot(filename="Rplot", type=c("wmf", "png", "jpeg", "jpg", "bmp", "ps", "pdf"), device=dev.cur())
```

The argument `filename` is the name of the file under which the plot should be saved; `type` is the file type (Windows metafile, PNG, JPEG, BMP, PostScript or PDF) and `device` is the device number of the window with the plot to be saved (by default, the active window). Note that the available file types may depend on your operating system.

```r
> hist(runif(100))
> savePlot(filename="mygraph.png", type="png")
```
Two other instructions can be used in this context:

- `dev.copy2eps(file="mygraph.eps")`
- `dev.copy2pdf(file="mygraph.pdf")`

which respectively create Postscript and PDF files.

5.1.2 Splitting the graphics window: `layout()`

If you want to draw several plots in the same window, R offers the possibility of splitting that window in as many boxes as needed.

A first possibility is the function `par()` with the argument `mfrow` (read the warning in Section 5.7 about the function `par()`). For instance, the following example splits the graphics window into three rows and two columns. Every time you call the drawing of a function, one of the small boxes is filled, row by row (the command `mfcol` is used to fill column by column), as shown in the following figure:
The function `layout()` is used to get a more sophisticated split than with the function `par()`. The following example shows how this splitting is specified in an intuitive way thanks to the argument `mat`, to draw five separate plots.

```r
> mat <- matrix(c(2,3,0,1,0,0,0,4,0,0,4,0,0,5),4,3,byrow=TRUE)
> mat
     [,1] [,2] [,3]
[1,]    2    3    0
[2,]    1    0    0
[3,]    0    4    0
[4,]    0    0    5
```
> `layout(mat)`

![Diagram of layout(mat)](image)

Fig. 5.2: Potential of the function `layout()`.

**Tip**

To display the previous figure in R, use the instruction `layout.show(5)`.

Every time you call the drawing of a function, the plots are displayed in order in the numbered boxes, in increasing order of the box numbers.

Also, note that with the argument `widths`, you can specify the respective relative widths of the columns of `mat`. The same can be done for the heights of rows with the argument `heights`. 
SECTION 5.2 Low level drawing functions

5.2.1 The functions plot() and points()

The function plot() is the generic function to draw plots. It takes as input argument the coordinates of the points to draw.

Warning

You can also use the function plot() on an R object for which a graphical method is defined. Examples are given in chapters 12 and 13.

Here are the most useful arguments of this function.
5.2 Low level drawing functions

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>Vector of x coordinates of points to draw.</td>
</tr>
<tr>
<td>y</td>
<td>Vector of y coordinates of points to draw.</td>
</tr>
<tr>
<td>type</td>
<td>Specify the type of plotting: &quot;p&quot; for points, &quot;l&quot; for lines, &quot;b&quot; for both, &quot;c&quot; for empty points joined by lines, &quot;o&quot; for overplotted points and lines, &quot;h&quot; for vertical lines, &quot;s&quot; for stair steps and &quot;n&quot; to plot nothing (but to display the window, with axes).</td>
</tr>
<tr>
<td>main</td>
<td>Specify the main title.</td>
</tr>
<tr>
<td>sub</td>
<td>Specify the subtitle.</td>
</tr>
<tr>
<td>xlab</td>
<td>Specify the label of the x axis.</td>
</tr>
<tr>
<td>ylab</td>
<td>Specify the label of the y axis.</td>
</tr>
<tr>
<td>xlim</td>
<td>Vector of length 2. Specify the lower and upper bound for the x axis.</td>
</tr>
<tr>
<td>ylim</td>
<td>Vector of length 2. Specify the lower and upper bound for the y axis.</td>
</tr>
<tr>
<td>log</td>
<td>Character string which contains &quot;x&quot; (respectively &quot;y&quot;, &quot;xy&quot; or &quot;yx&quot;) if the x axis (respectively the y axis, both) is to be logarithmic.</td>
</tr>
</tbody>
</table>

```r
> plot(1:4, c(2,3,4,1), type="b", main="Main title",
+       sub="Subtitle", xlab="Label for x", ylab="Label for y")
```

![Plot](image)

Fig. 5.4: The function `plot()`.

Note that successive calls of the function `plot()` create a new plot every time, which replaces the previous one (unless the graphics window has been split, as explained above). The function `points` can remediate this issue by overlaying the new plot on top of the old one. It takes the same arguments as `plot()`. 
> points(1:4,c(4,2,1,3),type="l")

Fig. 5.5: The function `points()`.

**Tip**

The function `approx()` provides a linear or constantwise interpolation between points.

### 5.2.2 The functions `segments()`, `lines()` and `abline()`

The functions `segments()` and `lines()` are used to join points with line segments, added on to a pre-existing plot.
5.2 Low level drawing functions

> plot(0,0,"n")
> segments(x0=0,y0=0,x1=1,y1=1)
> lines(x=c(1,0),y=c(0,1))

The function *abline()* is used to draw a straight line of equation $y = a + bx$
(specified by the arguments $a$ and $b$), or a horizontal (argument $h$) or vertical (argument $v$) line.

> plot(0,0,"n");abline(h=0,v=0);abline(a=1,b=1)
5.2.3 The function `arrows()`

This function is used to draw arrows between pairs of points. It takes an argument `length` to indicate the size of the arrow head.
5.2 Low level drawing functions

> x <- runif(12); y <- runif(12)
> i <- order(x,y); x <- x[i]; y <- y[i]
> plot(x,y)
> s <- seq(length(x)-1)
> arrows(x[s], y[s], x[s+1], y[s+1], length=0.1)

Fig. 5.8: The function `arrows()`.

5.2.4 The function `polygon()`

As the name suggests, this function is used to draw polygons, and to fill in a polygon with a specified colour.

**Do it yourself**

Enter the following command in the R console:

```r
example(polygon)
```

**Tip**

The command `polygon(locator(10,"l"))` is used to draw a ten-edge polygon by clicking in the graphics window on the points where the polygon vertices should be.
5.2.5 The function curve()

This function is used to draw a curve in a Cartesian coordinate system, on the interval specified by the bounds from and to.

> curve(x^3-3*x, from=-2, to=2)

Note that the argument add=TRUE can be used to indicate that the curve should be overlaid on a pre-existing plot.

Do it yourself

Use the following instruction to draw the density histogram of 10,000 random values from a normal distribution:

hist(rnorm(10000), prob=TRUE, breaks=100)

Use the function curve() to overlay on top of this histogram the density function of a N(0, 1) distribution, given by the function dnorm().
5.3 Managing colours

5.2.6 The function box()

This function is used to add a box around the current plot. The argument bty manages the type of box; the argument lty manages the type of line used to draw the box. Note that by default, the function plot() adds a box, unless it is given the argument axes=FALSE.

```r
> plot(runif(7), type = "h", axes = FALSE)
> box(lty = "1373")
```

![Fig. 5.10: The function box().](image)

5.3.1 The function colors()

This function returns the names of the 657 colours known to R.

Tip

If you want to get the different shades of orange, you can use the instruction

```r
> colors()[grep("orange", colors())]
[1] "darkorange" "darkorange1" "darkorange2" "darkorange3"
```
These colours can be used in your plots, for example with the argument \texttt{col} of the function \texttt{plot()}
.

\begin{verbatim}
> plot(1:10,runif(10),type="l",col="orangered")
\end{verbatim}

\begin{figure}
\centering
\includegraphics[width=0.5\textwidth]{example.png}
\caption{The argument \texttt{col} of function \texttt{plot()}.}
\end{figure}

\textbf{See also}

Note that you can also change the colour of the other elements of the plot, such as the axes or the title. To this end, refer to Section 5.7, page 174, which deals with the function \texttt{par()}. 

\subsection*{5.3.2 Hexadecimal colour coding}

\texttt{R} gives the possibility of using hexadecimal colour coding, for example with the argument \texttt{col} of the function \texttt{plot()}. Each colour is coded as its decomposition into three base colours: red, green and blue. Each component can take a value between 0 and 255 (0: complete absence of the colour; 255: saturation of the colour).
5.3 Managing colours

Hexadecimal coding of these 256 values gives codes between 00 and FF.

Here are few examples of colours:

Black: #000000  
White: #FFFFFF  
Almond green: #B2C46B  
Lemon yellow: #FFFF3C  
Peacock blue: #048B9A  
Midnight blue: #10076B

Note that you can use the function `rgb()` to get the hexadecimal code of a colour from its decomposition into red, green and blue.

```r
> rgb(red=26,green=204,blue=76,maxColorValue = 255)
[1] "#1ACC4C"
> rgb(red=0.1,green=0.8,blue=0.3)
[1] "#1ACC4D"
```

The function `col2rgb()` does the reverse operation:

```r
> col2rgb("#1ACC4C")
[,1]
red 26
green 204
blue 76
```

You can even get transparency, with the argument `alpha` of the function `rgb()`:

```r
> curve(sin(x),lwd=30,col=rgb(0.8,0.5,0.2),xlim=c(-10,10))
> curve(cos(x),lwd=30,col=rgb(0.1,0.8,0.3,alpha=0.2),add=T)
```

![Image](image.png)

Fig. 5.12: The argument `alpha` of function `rgb()`. 
If your graphics card allows it, R can thus handle up to $256^3$ colours, or over 16 million colours. The next example uses the function `rainbow()` and should give you an idea of this range.

```r
> pie(rep(1, 200), labels = "", col = rainbow(200), border = NA)
```

![Rainbow Pie Chart](image)

Fig. 5.13: An example using function `rainbow()`.

You can also add to R the package `RColorBrewer`. This package can be used to automatically create ideal colour palettes for beautiful presentations: shades of a colour, complementary or diverging colours.
5.3 Managing colours

> require("RColorBrewer")
> display.brewer.all()

Fig. 5.14: The function `display.brewer.all()` from package `RColorBrewer`.

5.3.3 The function `image()`

This function creates and displays a grid of coloured or grey-scale rectangles. The rectangles are also called pixels (picture elements). It can be used to display 3D or spatial data, i.e. images.

> X <- matrix(1:12, nrow=3)
> X

```
[1,] 1  4  7 10
[2,] 2  5  8 11
[3,] 3  6  9 12
```
> colours <- c("orange","orangered","red","lightblue",
+ "blue", "white", "lightgrey", "grey",
+ "darkgrey","yellow","green","purple")
> image(X,col=colours)
> text(rep(c(0,0.5,1),4),rep(c(0,0.3,0.7,1),each=3),1:12,cex=2)

![Image](image.png)

**Fig. 5.15:** The function `image()`.  

The numbers in the boxes were added using the function `text()` which is introduced later on.

**Warning**

Beware of how the coloured rectangles are organized: left to right and bottom to top. It is therefore an anticlockwise 90 degrees rotation of the display of the contents of the matrix `X`.

You can get a display coherent with how the data are organized in the matrix `X`, as follows:
> image(as.matrix(rev(as.data.frame(t(X)))),col=colours)
> text(rep(c(0,0.33,0.67,1),each=3),rep(c(1,0.5,0),4),1:12,cex=2)

Fig. 5.16: The function `image()` with a coherent display of the data.

**Do it yourself**

Install and load the package `caTools`. Use the function `read.gif()` of this package to read the file `http://www.biostatisticien.eu/springeR/R.gif`. Use the function `image()` to display it in R. Use the colours given by `read.gif()` and display the image in the correct orientation.

**SECTION 5.4**

Adding text

### 5.4.1 The function `text()`

This function is used to add text to a plot. A very interesting feature is that it can also be used to add mathematical formulae. In addition to the string itself, you need to specify the x and y coordinates of the center of the string. To display a mathematical expression, use the function `expression()`. The `bquote()` function can also be useful.
> plot(1:10,1:10,xlab=bquote(x[i]),ylab=bquote(y[i]))
> text(3,6,"some text")
> text(4,9,expression(widehat(beta) == (X^T * X)^{-1} * X^T * y))
> p <- 4; text(8,4,bquote(beta[.(p)])) # Combining "math" and numerical variables.

Fig. 5.17: The function text().

Tip

Use the command demo(plotmath) to see the various possibilities of adding mathematical expressions to a plot. This will also show the relevant commands.

Do it yourself

Plot a point at the coordinates (1, 1). Then use the function text() to add the text "ABC", also at the coordinates (1, 1). Observe the effect of the argument pos, which takes the values 1 (below), 2 (left), 3 (above) or 4 (right).
5.4.2 The function `mtext()`

This function is used to add text in the margins of the graphics window. It can also be used to add mathematical formulae.

It takes an argument `side` (1=bottom, 2=left, 3=top or 4=right) to specify which margin the text should be added in.

```r
> plot(1:10,1:10)
> mtext("bottom",side=1)
> mtext("left",side=2)
> mtext("top",side=3)
> mtext(expression(x^2+3*y+hat(beta)),side=4)
```

![Graph](image_url)

Fig. 5.18: The function `mtext()`.

### SECTION 5.5

**Titles, axes and captions**

5.5.1 The function `title()`

This function is used to add titles to a plot: a main title above the plot with the argument `main`, a subtitle below the plot with the argument `sub`, a label for the x axis with the argument `xlab`, and a label for the y axis with the argument `ylab`. Note that these arguments can also be specified directly when calling graphical functions such as `plot()`.
> plot.new()
> box()
> title(main = "Main title", sub = "Subtitle",
+ xlab = "x label", ylab = "y label")

```
    Main title
   
   y label

   x label
   Subtitle
```

Fig. 5.19: The function title().

**Tip**

A title can be written on several lines, thanks to the carriage return character "\n".

> plot(1:10,main="Title on\n three\n lines",xlab="",ylab="")

```
    Title on
   three
   lines
```

Fig. 5.20: Plot title on several lines.
5.5 Titles, axes and captions

5.5.2 The function `axis()`

This function adds an axis to a pre-existing plot. You can specify on which side to draw the axis, the position of ticks, and several other arguments.

**Note**

In general, you will only need the function `axis()` when you wish to control the details of the axes. To this end, you can first draw a plot (for example with the function `plot()`) without the axes, with the argument `axes=FALSE`.

Here are a few of the main arguments of the function `axis()`.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>side</td>
<td>Specify on which side to draw the axis: <code>side=1</code> (below), <code>side=2</code> (left), <code>side=3</code> (above), <code>side=4</code> (right).</td>
</tr>
<tr>
<td>at</td>
<td>Specify where to draw the ticks.</td>
</tr>
<tr>
<td>labels</td>
<td>Either a boolean to specify whether the ticks should be annotated, or a character string specifying the annotation at the ticks.</td>
</tr>
<tr>
<td>tick</td>
<td>Boolean specifying whether the ticks should be drawn.</td>
</tr>
<tr>
<td>col</td>
<td>Colour of the axis.</td>
</tr>
</tbody>
</table>

Other arguments are available and are described in the online help.

```r
plot.new()
lines(x=c(0,1),y=c(0,1),col="red")
axis(side=1,at=c(0,0.5,1),labels=c("a","b","c"),col="blue")
```

![Diagram](image.png)

Fig. 5.21: The function `axis()`.
5.5.3 The function \texttt{legend()} 

This function is used to add a caption to a pre-existing plot. Here are a few of its arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x, y)</td>
<td>Specify the coordinates of the position of the caption on the plot.</td>
</tr>
<tr>
<td>\texttt{legend}</td>
<td>Vector of character strings or expressions to display in the caption.</td>
</tr>
<tr>
<td>\texttt{fill}</td>
<td>Vector of colours to fill the background of the caption box.</td>
</tr>
<tr>
<td>\texttt{lty,lwd}</td>
<td>Integer. Line type or line width for lines in the legend. You must specify one of these arguments to get lines in the legend.</td>
</tr>
<tr>
<td>\texttt{col}</td>
<td>Vector of colours of points or lines in the legend.</td>
</tr>
</tbody>
</table>

```r
> plot(1:4,1:4,col=1:4)
> legend(x=3,y=2.5,legend=c("a","b","c","d"),fill=1:4)
```

Fig. 5.22: The function \texttt{legend()} with squares.
5.6 Interacting with the plot

> plot(1:4,1:4,col=1:4,type="b")
> legend(x=3,y=2.5,legend=c("a","b","c","d"),col=1:4,lty=1)

Fig. 5.23: The function \texttt{legend()} with line segments.

Many other arguments are available and are described in the online help.

\section*{SECTION 5.6 Interacting with the plot}

\subsection*{5.6.1 The function \texttt{locator()}}

It is used to place a point on a plot, or to get its coordinates with a click of the mouse. It can also be useful to add text (or a caption) at a specific location, thanks to the mouse.

\textbf{Do it yourself}

Enter the following instructions, then click anywhere on the plot you get.

\begin{verbatim}
plot(1,1)
\text{text(locator(1),labels="Here")} # Click on the graphics window.
\end{verbatim}
5.6.2 The function identify()

It is used to identify and mark points already present on a plot. The following practical should help you understand this function.

Do it yourself

Enter the following instructions, then click next to points on the plot. Use a right-click to exit the interactive mode.

```r
> plot(swiss[,1:2])
> x <- identify(swiss[,1:2],labels=rownames(swiss))
> x
```

SECTION 5.7

Fine-tuning graphical parameters: par()

The function `par()` takes many arguments to fine-tune your plots. Use this function to set (or query) general graphical parameters.

Here is how to use this instruction:

- `par(arg-name)` outputs the default value of the parameter `arg-name` of the function `par()`;
- `par(arg-name=val)` changes the value of the parameter `arg-name` to the value `val`;
- `par()` returns the list of all graphical parameters currently in use, as well as the current values.

Warning

Before changing the values of parameters of the function `par()`, you should save the old values. That way, you can restore them later if needed.

```r
# Save the default values of par().
save.par <- par(no.readonly = TRUE)
# Now we can change some parameters.
par(bg="red")
# Then restore the old values.
par(save.par)
```
Before we present the detailed use of this function, it is worth noting that the graphics window (also called device region) includes the figure region, which in turn includes the plot region. Figure 5.24 illustrates this.

Here is an (almost complete) list of the various parameters of the function \texttt{par()}, along with a short description. We have organized them in groups to make it easier to find relevant parameters.

- **Managing the graphics window**

  Table 5.1: Parameters to manage the graphics window.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{ask}</td>
<td>Boolean. If \texttt{TRUE}, the user is prompted to press \texttt{ENTER} before a new plot is drawn. Use \texttt{devAskNewPage()} instead.</td>
</tr>
<tr>
<td>\texttt{din}</td>
<td>Dimensions ((\texttt{c(width, height)})) of the graphics window, in inches (stands for device region inches).</td>
</tr>
<tr>
<td>\texttt{fig}</td>
<td>A numeric vector of the form (\texttt{c(x1, x2, y1, y2)}) giving the normalized device coordinates of the figure region, in which the plot will be drawn.</td>
</tr>
<tr>
<td>\texttt{fin}</td>
<td>A numeric vector of the form (\texttt{c(width, height)}) giving the size of the figure region, in inches (stands for figure region inches).</td>
</tr>
<tr>
<td>\texttt{mai}</td>
<td>A numeric vector of the form (\texttt{c(bottom, left, top, right)}) giving the size of the margins, in inches.</td>
</tr>
<tr>
<td>\texttt{mar}</td>
<td>A numeric vector of the form (\texttt{c(bottom, left, top, right)}) giving the number of margin lines on the four sides of the plot. The default value is (\texttt{c(5, 4, 4, 2)} + 0.1).</td>
</tr>
<tr>
<td>\texttt{mex}</td>
<td>\texttt{mex} is an expansion factor for the size of the font used to describe the coordinates in the plot margins. Note that this does not change the font size, but rather specifies, as a multiple of \texttt{csi}, the font size to convert between \texttt{mar} and \texttt{mai}, and between \texttt{oma} and \texttt{omi}. Its value is 1 when the device is opened, and is reinitialized when the layout is changed (\texttt{cex} is also reinitialized).</td>
</tr>
<tr>
<td>\texttt{mfcol}, \texttt{mfrow}</td>
<td>A vector of the form (\texttt{c(nl, nc)}). The successive plots (or multi-figures) will be drawn in a matrix of size (\texttt{nl})-by-(\texttt{nc}) in the graphics window, filled respectively by -columns- (\texttt{mfcol}) or by -rows- (\texttt{mfrow}). Consider the alternatives: \texttt{layout()} and \texttt{split.screen()}.</td>
</tr>
<tr>
<td>\texttt{mfg}</td>
<td>A numeric vector of the form (\texttt{c(i, j)}) where (i) and (j) indicate the cell of the figures matrix in which the next plot should be drawn. The figures matrix must have been pre-defined with one of the parameters \texttt{mfcol} or \texttt{mfrow}.</td>
</tr>
<tr>
<td>\texttt{mgp}</td>
<td>The margin line (in units of \texttt{mex}) for the axis titles, labels and lines. The default value is (\texttt{c(3, 1, 0)}).</td>
</tr>
<tr>
<td>\texttt{new}</td>
<td>Boolean, by default \texttt{FALSE}. If set to \texttt{TRUE}, the next high-level graphical command (in fact \texttt{plot.new()}) will not erase the old plot and will overlay the new plot.</td>
</tr>
<tr>
<td>\texttt{oma}</td>
<td>A vector of the form (\texttt{c(bottom, left, top, right)}) giving the region outside the margins, in NDC (= normalized device coordinates), i.e. as a proportion (in [0,1]) of the graphics window.</td>
</tr>
<tr>
<td>\texttt{omi}</td>
<td>A numeric vector of the form (\texttt{c(bottom, left, top, right)}) giving the size of the outer margins, in inches.</td>
</tr>
<tr>
<td>\texttt{pin}</td>
<td>The dimensions of the plot region, in inches (\texttt{c(width, height)}).</td>
</tr>
<tr>
<td>\texttt{plt}</td>
<td>A vector of the form (\texttt{c(x1, x2, y1, y2)}) giving the coordinates of the plot region as fractions of the current figure region.</td>
</tr>
<tr>
<td>\texttt{pty}</td>
<td>A character specifying the plot region type: &quot;s&quot; generates a square plot region and &quot;m&quot; generates the maximal plot region.</td>
</tr>
<tr>
<td>\texttt{usr}</td>
<td>A vector of the form (\texttt{c(x1, x2, y1, y2)}) giving the extreme values of the user coordinates of the plot region. If a log scale is used (i.e. \texttt{par(&quot;xlog&quot;)} is \texttt{TRUE}), then the limits in (x) are (10^{\texttt{par(&quot;usr&quot;)}[1:2]}). The same goes for the limits in (y).</td>
</tr>
<tr>
<td>\texttt{xpd}</td>
<td>A boolean or \texttt{NA}. If \texttt{FALSE}, all plots are attached to the plot region. If \texttt{TRUE}, all plots are attached to the figure region. If \texttt{NA}, all plots are attached to the plot window. See also \texttt{clip()}.</td>
</tr>
</tbody>
</table>

* An asterisk has been added to parameters which cannot be modified by the user (read only). The following plot should help you better understand some of these parameters.
Fig. 5.24: Figure illustrating the fine management of graphical parameters.
5.7: Fine-tuning graphical parameters: `par()`

- Managing colours

Table 5.2: Parameters to manage colours.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bg</td>
<td>Background colour of device region</td>
</tr>
<tr>
<td>col</td>
<td>Colour of plot</td>
</tr>
<tr>
<td>col.axis</td>
<td>Colour of axis annotations.</td>
</tr>
<tr>
<td>col.lab</td>
<td>Colour of x and y labels.</td>
</tr>
<tr>
<td>col.main</td>
<td>Colour of main title.</td>
</tr>
<tr>
<td>col.sub</td>
<td>Colour of subtitles</td>
</tr>
<tr>
<td>fg</td>
<td>Colour of foreground (axes and box around the plot). Sets col to the same value.</td>
</tr>
</tbody>
</table>

See how these parameters can be put in use:

```r
> par(bg="lightgray",col.axis="darkgreen",col.lab="darkred",
+     col.main="purple",col.sub="black",fg="blue")
> curve(cos(x),xlab="xlab in darkred",main="Title in purple",
+     xlim=c(-10,10),sub="sub in black")
> curve(sin(x),col="blue",add=T)
```

Fig. 5.25: Managing the colours of a plot.
Managing text

- Managing text displayed on a plot.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>adj</td>
<td>The value of <code>adj</code> determines how character strings are adjusted in <code>text()</code>, <code>mtext()</code> and <code>title()</code>. A value of 0 leads to left-adjusted text; 0.5 to centred text and 1 to right-adjusted text. Any value in [0, 1] is allowed, and some values outside this interval sometimes also work. Note that the argument <code>adj</code> to the function <code>text()</code> also allows <code>adj = c(x, y)</code> for different adjustments in x and in y. Note that for <code>text()</code>, the text is adjusted relatively to a point, whereas for <code>mtext()</code> and <code>title()</code>, it is adjusted relatively to the plot region or graphical window.</td>
</tr>
<tr>
<td>ann</td>
<td>If set to <code>FALSE</code>, high-level graphical functions will not add annotations to plots they produce (axes and main title). By default, annotations are added.</td>
</tr>
<tr>
<td>cex</td>
<td>A numeric value giving the character expansion coefficient for text and symbols on the plot, relatively to a reference value.</td>
</tr>
<tr>
<td>cex.axis</td>
<td>Character expansion coefficient for axes annotations.</td>
</tr>
<tr>
<td>cex.lab</td>
<td>Expansion for x and y labels.</td>
</tr>
<tr>
<td>cex.main</td>
<td>Expansion for main title.</td>
</tr>
<tr>
<td>cex.sub</td>
<td>Expansion for subtitles.</td>
</tr>
<tr>
<td>cin</td>
<td>Size of characters in inches <code>c(width, height)</code>.</td>
</tr>
<tr>
<td>crw</td>
<td>Size of characters in pixels <code>c(width, height)</code>.</td>
</tr>
<tr>
<td>crt</td>
<td>Numeric value specifying (in degrees) how various characters must be rotated. Must be a multiple of 90. Compare with <code>srt</code> which rotates character strings.</td>
</tr>
<tr>
<td>csi</td>
<td>Height of characters in inches. Identical to <code>par(&quot;cin&quot;)[2]</code>.</td>
</tr>
<tr>
<td>cxy</td>
<td>Size of the characters <code>c(width, height)</code> in units expressed relatively to the user coordinates <code>par(&quot;cxy&quot;)</code> is equal to <code>par(&quot;cin&quot;)/par(&quot;pin&quot;)</code> times a scaling factor in the user coordinates. Note that <code>c(strwidth(ch), strheight(ch))</code> for a given character string <code>ch</code> is usually much more accurate.</td>
</tr>
<tr>
<td>family</td>
<td>Name of a font family. Maximal size is 200 bytes. Each plot device puts this name in relation with a description of the font specific to the device. The default value is &quot;&quot;, which means that the default font is used (see the device help file for further details). Other oft-used values are serif, sans and mono; Hershey fonts are also available. This can be specified in the function <code>text()</code>.</td>
</tr>
<tr>
<td>font</td>
<td>An integer specifying the font to use for text. In general, 1 corresponds to ordinary text, 2 to bold, 3 to italics and 4 to bold italics. 5 should be symbol font (Adobe encoding).</td>
</tr>
<tr>
<td>font.axis</td>
<td>Font for axis annotations.</td>
</tr>
<tr>
<td>font.lab</td>
<td>Font for labels of x and y axes.</td>
</tr>
<tr>
<td>font.main</td>
<td>Font for main title.</td>
</tr>
<tr>
<td>font.sub</td>
<td>Font for subtitles.</td>
</tr>
<tr>
<td>ps</td>
<td>Integer. Size of text, in points (but not of symbols).</td>
</tr>
<tr>
<td>srt</td>
<td>Character string rotation, in degrees. See the comment on <code>crt</code>. Only supported by <code>text()</code>.</td>
</tr>
</tbody>
</table>

* An asterisk indicates arguments which cannot be modified by the user (read only).

Here is an example of use of the arguments `adj` and `srt`:

```r
> par(mfrow = c(1, 3))
> vals <- c(0, 0.5, 1)
> for (adj in vals) {
+ par(adj = adj)
+ plot(0, main = paste("adj =", adj), col.lab = "red",
+ col.main = "red", type = "n")
+ text(1, 0, "abc", col = "red", cex = 2)
+ abline(h = 0, lty = 2)
+ abline(v = 1, lty = 2)
+ }
> abline(v=0.8,h=-0.5,lty=2)
> text(0.8, -0.5, "abc", col = "red", cex = 2, adj=c(0,1))
> abline(h=0.5,v=0.5,lty=2)
```
5.7: Fine-tuning graphical parameters: `par()`

```r
> text(0.8, 0.5, "ABC", col="red", cex=2, adj=c(0.5, 0.5), srt=120)
```

This second example shows how to use different fonts:

```r
> par(cex.axis=1.5)
> plot(1:5, y=rep(1,5), type="n", font.axis=2, font.lab=3, xlab="xlab in italics", ylab="", font.main=4, main="Title in bold italics", font.sub=5, sub="Subtitle in symbol font")
> text(2, 1.2, "Normal text")
> par(ps=30)
> text(3, 1, "A Hershey font", family="HersheyScript")
> par(ps=14)
```

Fig. 5.26: Example of use of the arguments `adj` and `srt`. 
Fig. 5.27: Using different fonts on a plot.

Tip

To see all symbols and fonts available in R, use the following command:

demo(Hershey)
5.7 Fine-tuning graphical parameters: par()

- Managing axes

Table 5.4: Parameters to manage axes.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bty</td>
<td>Character string to specify the type of box around the plot (the axes). If bty is one of &quot;o&quot; (default value), &quot;l&quot;, &quot;n&quot;, or &quot;j&quot; the box looks like the corresponding character. A value of &quot;m&quot; hides the box.</td>
</tr>
<tr>
<td>lab</td>
<td>Numeric vector of the form c(x, y, len) modifying how the axes are annotated. The values of x and y (approximately) specify the number of ticks on the x and y axes. len specifies the size of the labels. The default value is c(5, 5, 7). Note that this only affects the values of the arguments xaxp and yaxp when the coordinates system is put in place, and is not used when the axes are drawn. len is not implemented yet.</td>
</tr>
<tr>
<td>las</td>
<td>Number in the set (0, 1, 2, 3). Style of the axis labels. 0=always parallel to the axis (default), 1=always horizontal, 2=always orthogonal to the axis, 3=always vertical. Note that the argument srt of par(), which manages the rotation of character strings, does not affect axis labels.</td>
</tr>
<tr>
<td>tck</td>
<td>Length of tick marks on axes, as a fraction of the minimum of the height and width of the drawing region. If tck := 0.5, then it is interpreted as a fraction of the relevant side, and if tck=1 then a grid is drawn. The default (tck = 0) sets tck = 0.5.</td>
</tr>
<tr>
<td>tcl</td>
<td>Length of the tick marks as a fraction of the height of a line of text. The default value is 0.5. Entering text at NA sets tck = 0.81.</td>
</tr>
<tr>
<td>xaxp</td>
<td>A vector of the form c(x1, x2, n) giving the coordinates of the extreme ticks and the number of intervals between ticks, when par(&quot;xlog&quot;) is FALSE. Otherwise, when the scale is logarithmic, the three values have different meanings. See the online help for details. See also axTicks().</td>
</tr>
<tr>
<td>xaxs</td>
<td>Style for the intervals on the x axis. Possible values: &quot;r&quot;, &quot;s&quot;, &quot;d&quot;, &quot;n&quot;, &quot;o&quot;, &quot;u&quot;, &quot;f&quot;, &quot;h&quot;, or &quot;l&quot;. The style is usually controlled by the data range, or by xlim if it is specified. The style &quot;r&quot; (regular) first enlarges the data range by 4 % on both sides, then finds an axis with pretty labels which fits in the range. The style &quot;i&quot; (internal) only finds an axis with pretty labels which fits the original data range. The style &quot;n&quot; (standard) finds an axis with pretty labels in which the original data range is included. The style &quot;e&quot; (extended) is similar to the style &quot;s&quot;, but it also leaves space to draw symbols inside the bounding box. The style &quot;d&quot; (direct) specifies that the current axes must be used for subsequent plots. As of writing, only the styles &quot;r&quot; and &quot;i&quot; are implemented.</td>
</tr>
<tr>
<td>xaxt</td>
<td>A character to specify the type of x axis. A value of &quot;n&quot; implies that an axis is created, but not drawn. The standard value is &quot;r&quot;.</td>
</tr>
<tr>
<td>xlog</td>
<td>Boolean (see log in plot.default()). If TRUE, a logarithmic scale is used (for example, after plot(1, log = &quot;x&quot;). For a new graphics window, the default is FALSE, i.e. a linear scale.</td>
</tr>
<tr>
<td>xaxp</td>
<td>A vector of the form c(y1, y2, n) giving the coordinates of the extreme tick marks and the number of intervals between these ticks, except for the logarithmic scale. See xaxs above.</td>
</tr>
<tr>
<td>xaxs</td>
<td>Style for the intervals on the y axis. See xaxs above.</td>
</tr>
<tr>
<td>xaxt</td>
<td>Character to specify the type of y axis. A value of &quot;n&quot; implies that the axis is created, but not drawn. The standard value is &quot;r&quot;.</td>
</tr>
<tr>
<td>xlog</td>
<td>Boolean, see xlog above.</td>
</tr>
</tbody>
</table>

A few of these parameters are used in the following example:

```r
# Enlarge the bottom margin to leave space for the x labels.
> par(mar = c(7, 4, 4, 2) + 0.1)
> # Define a box style, ten ticks in x and y, horizontal labels, and graduations of length 1 (which gives a grid)
> par(bty="7", col="blue", lab=c(10,10,1), las=1,tck=1)
> # Create a plot without the x axis and without x labels.
> plot(1 : 8, xaxt = "n", xlab = "")
> # Add the x axis with ticks only.
> axis(1, labels = FALSE)
> # Create the label vector.
> labels <- paste("Label", 1:8, sep = " ")
> # Add the x labels to the default ticks.
> text(1:8, par(usr)[3] - 0.25, srt = 45, adj = 1, + labels = labels, xpd = TRUE)
> # Add a subtitle at the bottom, on the sixth margin line (out
```
> mtext(1, text = "Labels for the X axis", line = 6)

Fig. 5.28: Labels on a plot.
5.7 Fine-tuning graphical parameters: \texttt{par()}

- **Lines and symbols**

Table 5.5: Parameters for \textbf{lines and symbols}.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>lend</code></td>
<td>End-of-line style. Can be specified with an integer or a character string: 0 or &quot;round&quot; means that a semi-circle is added at the end of a line; 1 or &quot;butt&quot; means that lines end straight; 2 or &quot;square&quot; means that a small square is added at the end of a line.</td>
</tr>
<tr>
<td><code>lheight</code></td>
<td>Line height multiplier. When a text extends over several lines, the height of the space between lines is found by multiplying the height of characters both by the current character expansion factor and by the line height multiplier. The default value is 1. Used in \texttt{text()} and \texttt{strheight()}.</td>
</tr>
<tr>
<td><code>ljoin</code></td>
<td>Line join style. Can be specified with an integer or a character string: 0 or &quot;round&quot; means a round join (default); 1 or &quot;mitre&quot; means a straight join; 2 or &quot;bevel&quot; means a bevelled join.</td>
</tr>
<tr>
<td><code>lmitre</code></td>
<td>Controls when straight joins are automatically converted to pointy joins. Must be greater than 1 and the default value is 10. Does not work on some peripherals.</td>
</tr>
<tr>
<td><code>lty</code></td>
<td>Line type. Can be specified by an integer (0=blank, 1=solid, 2=dashes, 3=dots, 4=dots and dashes, 5=long dashes, 6=two dashes), or by one of the character strings &quot;blank&quot;, &quot;solid&quot;, &quot;dashed&quot;, &quot;dotted&quot;, &quot;dotteddashed&quot;, &quot;longdashed&quot; or &quot;twodash&quot;. Note that &quot;blank&quot; uses invisible lines (so does not draw them). You can also give a character string (of length no more than 8) giving the length of the solid and empty segments. See the section \texttt{Line type specification} of the online help.</td>
</tr>
<tr>
<td><code>lwd</code></td>
<td>Line width in the plot (positive number), defaults to 1.</td>
</tr>
<tr>
<td><code>pch</code></td>
<td>Either an integer specifying a symbol or a character to replace small circles in point plots.</td>
</tr>
</tbody>
</table>

The following plot should help you better understand the arguments \texttt{lend} and \texttt{ljoin}.

![Figure 5.29: The arguments \texttt{lend} and \texttt{ljoin}](image)

The figure below shows the different symbols you can obtain with the argument \texttt{pch}. The type of points in a plot is controlled with the argument \texttt{pch}. Points 0 to 20
are of the same colour, controlled with the argument `col`. Points 21 to 25 also have a filling colour, controlled with the argument `bg` of the function `points()`.

Values of the argument `pch`:

```
0: ●
1: ○
2: ●
3: ○
4: ●
5: ○
6: ●
7: ○
8: ●
9: ○
10: ●
11: ○
12: ●
13: ○
14: ●
15: ○
16: ●
17: ○
18: ●
19: ○
20: ●
21: ○
22: ●
23: ○
24: ●
25: ○
```

Fig. 5.30: The argument `pch`.

The following figure shows how to use the arguments `lty` and `lwd`:

```r
> plot(1,1,type="n")
> for (i in 0:6) abline(v=0.6+i*0.1,lty=i,lwd=i)
> abline(v=1.3,lty="92",lwd=10)
```

Fig. 5.31: The arguments `lty` and `lwd`. 
There are other R packages to manage plots in a more advanced way. Space does not allow us to describe these packages in much detail. We shall simply give a few striking examples, in the hope that the advanced reader will want to find out more.

- **Package rgl**

  This package is used to create pretty 3D plots, with interactive viewpoint navigation using the mouse. Try the following commands to get an idea:

```r
demo(rgl)
demo(rgl)
example(rgl)
```

- **Package lattice**

  An entire book is dedicated to this package: [36]. The following example shows that in the package lattice, plots can be considered as objects (as in object-oriented programming), which some readers might find pleasing. For example, suppose that you have used the following commands to draw a graph, and that you realize you made a mistake in the title.

```r
x <- 1:100
y <- sin(x)
plot(x, y, type="l", main="Cosine plot")
```

The way to resolve this issue would be to redraw the entire figure, this time with the correct title.

```r
require(lattice)
xyplot(y ~ x, type="l", main="Cosine plot")
```

The following instruction can be used to change the title without redrawing the plot!

```r
update(trellis.last.object(), main="Sine plot")
```

- **Package ggplot2**

  We shall only mention the package ggplot2, which makes explicit the conceptual links between plots and statistical analyses. You can visit the website of this package at [http://had.co.nz/ggplot2](http://had.co.nz/ggplot2) and the website of the book devoted to it at [http://had.co.nz/ggplot2/book](http://had.co.nz/ggplot2/book).
5.1- What is the command `windows()` used for? And the command `dev.off()`?

5.2- Suppose you drew a plot with the command `curve(cos(x))`. Which R instruction would you use to save this plot as a PDF in a file called `myplot.pdf`?

5.3- Give a detailed explanation of the effect of the instruction `par(mfrow=c(3,2)).`

5.4- What is the function `layout()` used for?

5.5- Which command would you use to add a scatter plot to a pre-existing plot?

5.6- Which argument of the function `plot()` would you use to get points with dashes between them?

5.7- Name a function which draws a straight line.

5.8- What is the function `curve()` used for?

5.9- Which argument would you use to manage the colours in a plot?

5.10- Which function would you use to display an image? Give an instruction to display an image, the values of which are given in a matrix `X`, so that the output is coherent with the way `X` is displayed in the console.

5.11- Which function would you use to add text to a plot?

5.12- Which function would you use to find the coordinates of a point in a plot with a click of the mouse?

5.13- Give a detailed explanation of the effect of the instruction `par(ask=TRUE).`
5.14- Which argument of the function `par()` would you use to specify the type of line drawn by the function `curve()`?

5.15- Which argument of the function `par()` would you use to display other symbols instead of small circles in a scatter plot?

5.16- Give a list of instructions to display the following plot. The central axis system must be displayed in red. The cosine curve must be displayed in blue.

Worksheet

Creating various plots

A- Complex numbers

5.1- Reproduce the plot on complex numbers in Chapter 1 (page 46).
B- Flag of Canada

5.1- Install the package caTools.
5.2- Use the function `read.gif()` to read the image http://www.biostatisticien.eu/springer/canada.gif.
5.3- Display the image with the function `image()`.
5.4- Re-draw this flag in another window, using the functions `plot()`, `rect()` and `polygon()` (hint: use the function `locator()`).

C- Frequency tables

The following table represents scores of burning sensation for sixteen subjects in a study to test a new hydrogel bandage. The first column gives the subject number. The next columns give the score of burning sensation (on a scale from 1 to 4) for weeks 1 (W1) to 7 (W7).

<table>

</tbody>
</table>

We shall propose an interesting way to display these data.

5.1- For week W7, calculate the vector \((f_1, 1 - f_1, f_2, 1 - f_2, f_3, 1 - f_3, f_4, 1 - f_4)\) where \(f_i\) is the frequency of modality \(i\) \((1 \leq i \leq 4)\) observed in week W7 over the sixteen subjects. (Hint: use the functions `tabulate()`, `cbind()`, `t()` and `as.vector()`).
5.2- Now, use the function `apply()` to do the same calculation for all other weeks. Store the result in a matrix.
5.3- Use the function `barplot()` and the argument `col=c("black","white")` on this matrix. The plot you get gives an overview of the evolution of the variable Burning sensation over time.
5.4- Change the previous plot so that the bars representing frequencies are in red. Week numbers should be in blue, and at the top of the plot instead of the bottom. Modality numbers should be on the left, in blue. Add a title to the plot.
D- Anatomic images of the brain

Data acquired during Magnetic Resonance Imaging (MRI) of the brain are usually stored as a binary file with extension *.img. We shall see how to read and display such data.

5.1- Import the file http://www.biostatisticien.eu/springeR/anat.img, which contains the image of a single brain section of 256 × 256 pixels, using the function readBin(). These data can be treated as a sequence of 256×256 byte pairs (raw). Store these data in an object called bytes.

5.2- When the data were recorded, each pair of bytes was in fact written in reverse (for example, the pair 02 56 was recorded as 56 02). You therefore need to permute each byte pair. Store the result of this operation in x.

5.3- This sequence of byte pairs now needs to be transformed into numeric values which can be displayed graphically. With two bytes (such as 02 56), you can use the instruction as.numeric("0x0256") to get the corresponding decimal value (in this case, the result is 598). Transform x into decimal values and store the result in an object called values (hint: use the functions matrix(), apply() and paste()).

5.4- Recreate the matrix of size 256 × 256 containing the observations stored in values. Call this matrix X.

5.5- Use the function image() on X. Use a colour gradient of shades of grey with about one hundred shades, using the function gray().

5.6- Note that the R package AnalyzeFMRI does exactly that. After downloading the two files http://www.biostatisticien.eu/springeR/anat.img and http://www.biostatisticien.eu/springeR/anat.hdr, and after installing package AnalyzeFMRI, you could have got the exact same result by typing:

```r
require(AnalyzeFMRI)
Y <- f.read.volume("/path/to/anat.img") # Replace path.
image(X,col=gray(0:1000 / 1000))
```

E- Drawing the map of a region of France

The package maps includes maps of various countries. We shall use it to draw the borders of a French département.

5.1- Install and load the packages maps and mapdata.

5.2- Draw the map of France: map("france").

5.3- Get the data on borders of French regions:

```r
france <- map("france",plot=FALSE)
```

5.4- Display the contents of the object france and make sure you understand how it is organized. For example, note that latitude and longitude data are stored in france$x/france$y for each département in france$names (until the next NA).

5.5- Create a vector indNA containing the indices of missing values.
5.6- Create an object containing the name of the *département* of your choice (for example \texttt{depname <- "Gard"}).

5.7- Create an object called \texttt{inddept} containing the *département* index \texttt{depname} in the vector \texttt{france$names}.

5.8- Draw the map of your *département*.

5.9- Add a point for a place on the map. You can get the coordinates (latitude and longitude) of a place on the website \url{http://www.gpsvisualizer.com/geocode}.

**F- Representation of the geoid in France**

A geoid can be seen as a gravitation equipotential surface, going through the average sea level datum.

5.1- Import the file \url{http://www.biostatisticien.eu/springeR/raf98.gra} in a matrix, using the function \texttt{scan()}. First, read the associated file \url{http://www.biostatisticien.eu/springeR/geoidformat.txt} which gives a description of the file format.

5.2- Try to reproduce the plot available at \url{http://www.biostatisticien.eu/springeR/geoid.png}. Do not try to superpose the map of France yet (hint: use the functions \texttt{scan()}, \texttt{layout()}, \texttt{par()}, \texttt{image()}, \texttt{axis()}, \texttt{contour()}, \texttt{legend()} and \texttt{rainbow()}).
Chapter 6
Programming in R

Prerequisites and goals of this chapter

- Read all previous chapters first. A neophyte user can skim through this chapter on first reading. Indeed, it is well known that programming in a language requires a more advanced level than using a language.
- The aim of this chapter is to give the user the opportunity to develop new functions; in R, this corresponds to extending the language. The user can thus complete his comprehension of how R works.

SECTION 6.1
Preamble

The strength of the R system is that it includes a real programming language. We shall see that it offers very original programming concepts. The concept of objects is very present in R. Object-oriented programming as used in R is transparent for the user, in the sense that you do not need to understand the theory in order to use it. The same cannot be said for the developer who wishes to respect the spirit of R.

Practical problem
As an example, this chapter will tackle the resolution of the following practical problem. Suppose that some users, beginners in R, wish to discover programming in R by developing a few functions relative to the well-known least-squares methods, in the context of simple linear regression. He soon realizes that two specific tasks are of interest to him: first, output a summary with estimations and the coefficient

\[ \text{See for example http://en.wikipedia.org/wiki/Ordinary_least_squares} \]
of linear correlation; second, draw a scatter plot with the regression line. With his experience from previous chapters, this user finds it easy to produce these results from the command line. However, he would like to avoid having to type in several lines of commands every time he wishes to see the result of these two tasks, and so would like to develop two functions, easier to apply in a daily use of R. To this end, he will have the help of a more advanced user who can advise him every time he encounters a difficulty.

This practical problem should help the reader understand the use of the notions presented in this chapter.

SECTION 6.2

Developing functions

First of all, let us introduce some basic theoretical elements to explain how to create a function in R.

6.2.1 Quick start: declaring, creating and calling functions

Declaring a function is done with the following general form:

\[ \text{function(<list of arguments>) <body of the function>} \]

where

- \(<\text{list of arguments}>\) is a list of named (formal) arguments;
- \(<\text{body of the function}>\) represents, as the name suggests, the contents of the code to execute when the function is called.

Here is an example of function declaration:

\[
> \text{function(name) cat("Hello", name, ")!")}
\]

For R, a function is a specific object. Creating a function thus corresponds to affecting the object “R function” to a variable, the name of which corresponds to the function itself. For example, to create the function hello(), you can proceed as follows:

\[
> \text{hello <- function(name) cat("Hello", name, ")!")}
> \text{hello}
\]

For this function to be executed, the user needs to call the function, followed by the effective arguments listed in brackets. Recall that an effective argument is the value affected to a formal argument. We will use the terms calling argument and input argument as synonyms of effective argument.
6.2 Developing functions

6.2.2 Basic concepts on functions

6.2.2.1 Body of a function

The body of a function can be a simple R instruction, or a sequence of R instructions. In the latter case, the instructions must be enclosed between the characters { and } to delimit the beginning and end of the body of the function. Several R instructions can be written on the same line as long as they are separated by the character ;. When the body of the function includes several R instructions written on the same line, do not forget to enclose them between characters { and }. Recall that on a line, any code written after the character # is not interpreted by R and is taken to be a comment.

```r
> hello <- function(name) {
+   # Convert the name to upper case.
+   name <- toupper(name)
+   cat("Hello", name,"!")
+ }

> hello("Peter")
Hello PETER !
```

6.2.2.2 List of formal and effective arguments

In this section, we describe how to declare the list of formal arguments when defining a function, and how to input the list of effective arguments when calling a function.

### Declaring a function

When declaring a function, **all arguments are identified by a unique name.** Each argument can be associated with a default value. To specify a default value, use the character = followed by the default value, as when declaring a list object (list). When the function is called with no effective argument for that argument, the default value will be used. We have used this functionality many times in previous chapters, but we now know how to include it when developing new functions. Here is an example:

```r
> hello <- function(name="Peter") cat("Hello", name,"!")
> hello()
Hello Peter !
```

It seems useful to explain the difference between calling the name of the function `hello` and calling the function followed by brackets: `hello()`. The first form will
display the contents of the function, as with any other \texttt{R} object, whereas the second form will call the function (in this case, with no argument specified). To execute a function, you always have to add brackets, and list the effective arguments if necessary.

**Naming effective arguments**

In \texttt{R}, an effective argument can be entered by adding the name of the formal argument. Of course, this is of little interest when the function only depends on a single formal argument. Let us add to our function \texttt{hello()} the possibility of choosing a language, and see a few calls of this function.

\begin{verbatim}
> hello <- function(name="Peter",language="eng") {
+   cat(switch(language,fr="Bonjour",sp="Hola",eng="Hello"),name,"!")
+ }
> hello()
Hello Peter !
> hello(name="Ben")
Hello Ben !
> hello(language="fr")
Bonjour Peter !
\end{verbatim}

This functionality, combined with the ability to specify default values\footnote{The function \texttt{missing()} is also very useful for this kind of programming.}, allows the developer to define a function with an important list of formal arguments corresponding to call options. Users can then call this function without needing to input all effective arguments. For example, they can affect a value to the last formal argument without having to type in all the other effective arguments. This way, a single function can be used for what would have otherwise required several functions. This is a true specificity\footnote{It should be noted that many programming languages do not have this functionality.} of \texttt{R}, which allows an innovative programming mode. For example, read the help file on the functionalities of the function \texttt{seq()} with the various arguments \texttt{length.out} and \texttt{along.with}.

**Partial naming of effective arguments**

In the same context, a second functionality of \texttt{R} is that it allows calling a function without typing in the complete name of a formal argument. Consider the following calls of the function \texttt{hello()}:

\begin{verbatim}
> hello(lang="eng")
Hello Peter !
> hello(l="eng")
Hello Peter !
> hello(l="e")
Peter !
\end{verbatim}

The rule for determining the formal argument corresponding to a partial name is: in the ordered list of formal arguments of the function, the selected formal argument
is the **first** formal argument for which there is a match between the first letters of the argument name and the partial name given by the user.

**List of supplementary arguments “...”**

You can give a list of supplementary arguments with the syntax `...`. When calling the function, all “named” arguments which are not in the list of formal arguments are grouped in the structure `...`. In the body of the function, the user can then use the syntax `...` as if copy-pasting the list of supplementary named arguments. This begs for an example.

```r
> test.3points <- function(a="foo",...) print(list(a=a,...))
> test.3points("bar",b="foo")

$a
[1] "bar"
$b
[1] "foo"
```

Generally speaking, a rule of thumb for using the list of supplementary arguments `...` in the body of a function is that it should be used as an argument of one or several internal function calls.

---

**Advanced users**

When `...` is included in a list of arguments and is not in last position, “partial naming of arguments” will not work for all arguments after `...`. Indeed, a partial formal argument name is then considered as a formal argument in the supplementary list.

```r
> test.3points <- function(aa="foo",...,bb="bar") {
+   print(list(aa=aa,...,bb=bb))
> test.3points(a="bar",b="foo")

$aa
[1] "bar"
$b
[1] "foo"
$bb
[1] "bar"
```

Note that the value of the formal argument `aa` has been modified, but that `bb` did not change its value. The formal argument `b` was created. To change the value of the second formal argument `bb`, you need to use the complete name.

```r
> test.3points(a="bar",bb="foo")

$aa
[1] "bar"
$bb
[1] "foo"
```

A keen user of partial names might be surprised by the following output when using the function `paste(..., sep = " ", collapse = NULL)` if
he had taken the liberty of using the partial name (col) of the formal argument collapse:

```r
> paste(c("foo","bar"),col=" ", )
[1] "foo , " "bar , "
```

Since partial naming is ineffectual, col is considered as a second vector to paste, and the default options of the function `paste()` are used (i.e. `sep=" "` and `collapse=NULL`). To get the desired output, you need to use the complete name of the formal argument `collapse`.

```r
> paste(c("foo","bar"),collapse=" ", )
[1] "foo, bar"
```

**Tip**

Generally speaking, when you call a function, you need to specify the value of all formal arguments for which no default value is defined. If you do not, an error occurs. There are however two exceptions. The first corresponds to the case where the argument is not used in the body of the function; this of course useless and is probably due to a programming mistake. The second exception is when the developer allowed for this case in the body of the program, with the function `missing()`.

```r
> hello <- function(name) {
+ if(missing("name")) name <- "Peter"
+ cat("Hello",name,"!")
+ }
> hello()
Hello Peter !
```

### 6.2.2.3 Object returned by a function

The function `hello()` above does not return any object. It simply produces a display on the screen.

```r
> res <- hello()
Hello Peter !
> res
NULL
```

In previous chapters, we have often used R functions and saved the result as a variable (for example `x <- c(1, 5, 3)`), where the result of the base function `c()` is affected to the variable `x`). Since we are now interested in developing functions, let us examine how to create a function which returns an object (a result that is not ephemeral).
A general rule to return an object is to use the function `return()`. This instruction halts the execution of the code of the body of the function and returns the object between brackets. Here is an example:

```r
> hello <- function(name="Peter") {
  + return(paste("Hello",name,"!",collapse=" "))
} > hello()
[1] "Hello Peter !"
> message <- hello()
> message
[1] "Hello Peter !"
```

The first call of the function returns the string of characters object without affecting it to a variable. The result is thus displayed on the screen, as if the user had entered in the command line the object returned by the function. The second call does not produce any display: the result of the function is redirected to the variable `message`, as the last instruction above shows.

```
Note

It is possible to return an object without using the function `return()`. The rule is then that the returned object is the last object manipulated in the last instruction of the body of the function (i.e. just before exiting the function). In the previous example, we could therefore have omitted the function `return()`

```r
> hello <- function(name="Peter") {
  + paste("Hello",name,"!",collapse=" "))
} > hello()
[1] "Hello Peter !"
```

However, we discourage this practice because it does not always work, as shown below where we would expect that the function returns 10:

```
> function.without.return <- function() {
+ for (i in 1:10) x <- i
} > function.without.return()
```

Can you tell whether the following function returns an object? If yes, what is the content of this object?

```r
> hello <- function(name="Peter") {
+ msg <- paste("Hello",name,"!",collapse=" "))
} > hello()
```

What do you think when you see the output below?

```r
> hello()
```

There is no display, so it seems that no object is returned. But are you certain when you see the following example?

```r
> message <- hello()
> message
[1] "Hello Peter !"
```
The last manipulated object is indeed the variable msg. Affecting the output to the variable message does store the contents of the variable msg from the body of the function. R can sometimes be unsettling, but you will agree that this kind of usage is not rational and a developer would probably never find it useful.

Tip

If you wish to get the same behaviour as in the last example, i.e. that the function does not display anything when called but does return an object, it is more direct to use the function invisible() – the name of this function is clear enough.

```r
> hello <- function(name="Peter")
+ invisible(paste("Hello",name,"!",collapse=" "))
> hello()
> message <- hello()
> message
[1] "Hello Peter !"
```

6.2.2.4 Variable scope in the body of a function

The notion of variable scope is very important for a language which allows to develop functions. The main point is that variables defined inside the body of a function have a local scope during function execution. This means that a variable inside the body of a function is physically different from another variable with the same name, but defined in the workspace of your R session. Generally speaking, local scope means that a variable only exists inside the body of the function. After the execution of the function, the variable is thus automatically deleted from the memory of the computer. We are now going to modify our function hello() by inserting controls of the contents of variables.

```r
> message <- "hello Pierre !"
> message # Workspace initialization.
[1] "hello Pierre !"
> hello <- function(name="Peter",message="hello") {
+ print(message)
+ message <- paste(message,name,"!",collapse=" ")
+ print(message)
+ invisible(message)
+ }
> hello()
[1] "hello"
[1] "hello Peter !"
> message # Workspace has not been modified!
[1] "hello Pierre !"
> message <- hello()
[1] "hello"
[1] "hello Peter !"
```
6.2 Developing functions

> message # Workspace has been modified!
[1] "hello Peter !"
> message <- hello(message="Welcome")
[1] "Welcome"
[1] "Welcome Peter !"
> message # Workspace has been modified again!
[1] "Welcome Peter !"

A quick comment on the arguments of the function: contrary to what you might think, the variables `name` and `message` are not directly evaluated (initialized to the calling value or to the default value) before the execution of the body of the function. They are only initialized when they are first used in the body of the function. Recall that the function `missing()` is used to test whether a formal argument has been defined when calling the function. The only way for this functionality to be operational is by not evaluating the list of formal arguments at the beginning of the body of the function. Similarly, at the beginning of the body of the function, it is possible to get the effective call (with the completed list of arguments) by using the function `match.call()`.

> test.call <- function(aa="bar",...,bb="foo") {
  + print(match.call())
  + test.call(a="foo",b="bar")
}

Advanced users

The last function creation may not seem very useful, but once you are an advanced R developer, you might find a use to the result of the function `match.call()`. We shall not give details, but only a taste of what can be done in R. We shall modify the last function so that it returns the arguments split into two lists: one (called `function`) of effective arguments associated with formal arguments and one (called `misc`) of supplementary effective arguments. Note how partial naming of arguments is managed.

> test.call <- function(aa="bar",...,bb="foo") {
  + args <- as.list(match.call())[-1]
  + in <- names(args) %in% names(list(...))
  + list(function=args[!in],misc=args[in])
  +
  + test.call(a="foo",b="bar")
}

A few lines of code are enough to get the result: introspection is easy in R, and has many other features in the same context. We are not trying to get you to delve straight away into this kind of development, but wish to point out the possibilities of the language.
6.2.3 Application to the practical problem

After these theoretical explanations, our beginner user tries the following function codes for simple linear regression.

```r
mysummary.reg1 <- function(y, x) {
  aEst <- cov(x, y)/var(x)
  bEst <- mean(y) - aEst*mean(x)
  return(list(aEst=aEst, bEst=bEst, cor=cor(x,y)))
}

mydisplay.reg1 <- function(y, x) {
  aEst <- cov(x, y)/var(x)
  bEst <- mean(y) - aEst*mean(x)
  plot(x, y)
  abline(a=bEst, b=aEst)
}
```

Note that in old versions of R, you could write

```r
return(aEst=aEst, bEst=bEst, cor=cor(x,y))
```

but that this usage will be deprecated in future versions.

After loading these functions with a copy-paste or with the command `source()`, the user tests an uninteresting example.

```r
> y <- rnorm(10); x <- 1:10
> mysummary.reg1(y,x)
$\text{aEst}$
[1] -0.1019453
$\text{bEst}$
[1] 0.7822879
$\text{cor}$
[1] -0.4198245
```
6.2 Developing functions

> mydisplay.reg1(y,x)

![Graph](image.png)

Fig. 6.1: Result of the call of the function `mydisplay.reg1()`.

We shall see later on how these functions can be enriched.

### 6.2.4 Operators

Calling a function under the form `<function>(<list of call arguments>)` is not always easy. An example is the function `seq()`. Of these two equivalent forms, which one do you prefer?

> seq(1,3)

```
[1] 1 2 3
```

> 1:3

```
[1] 1 2 3
```

You probably prefer the second form, since it is more synthetic (no brackets) and is thus easier to manipulate, for example when using indices (of vectors, matrices...). This form corresponds to an operator. R uses operators internally.

There are two forms of operators:

- **unary operator** (one argument): `<operator> <argument1>`
- **binary operator** (two arguments): `<argument1> <operator> <argument2>`

where `<operator>` is the operator, and `<argument1>` and `<argument2>` are the effective arguments of the operator. Here is a partial list of operators used internally by R:
+, -, *, /, ^, %%, %/%, &, |, !, ==, !=, <, <=, >=, >.

A priori, these operators cannot be modified by the user. It is however possible to define extra operators. They are of the form `%<operator>%` and some are already available in the base system, for example `%in%` and `%o%` (seen in Chapter 3).

**Tip**

To display the source of the function (the operator) `%in%`, use the instruction: `get(%in%)`. You can see that it uses the function `match()` which you may find useful.

Suppose we wish a more synthetic way to concatenate strings of characters, which is normally done with the function `paste()`.

```r
> "%+%" <- function(ch1,ch2) paste(ch1,ch2,sep="")
> name <- "Peter"
> "The life of " %+% name %+% " is beautiful!"
[1] "The life of Peter is beautiful!"
```

Note that since the name of the function is not alphanumeric, it has to be put between quotation marks. It is of course up to you whether you prefer one or the other form. We are not trying to diminish the usefulness of the function `paste()`, which is a much richer function than the simple operator `%+%` we have created (the creation actually used the function `paste()`). We are rather trying to show the flexibility of R which allows, with a simple function definition, a simplification of the calling syntax.

**Tip**

You can use operators to define operations on sets, such as those presented on page 96. For example, the union between two sets `A` and `B` can be defined as:

```r
> "%union%" <- function(A,B) union(A,B)
> A %union% B
[1] 4 6 2 7 1 3
```

---

4 In fact, this group of operators can be used by a user when developing a new class of objects. But this matter is too advanced for this book!
6.2.5 R seen as a functional language

R is a functional language in the sense that almost any code execution in R is done by calling functions, possibly scattered with control structures. In fact, you may be surprised to learn that the following features of R are also controlled by functions. We have seen that simply calling an R object results in the display of its contents. In fact, in such an instruction, R calls (without notifying the user) the function `print()` with effective argument the name of the object. Because this function is often used in R, it has a particular status; we shall discuss this further later on. All assignment operations (i.e., instructions with `<-`) are handled by functions whose names include (no surprise here) the distinctive sign `<-`. Developing and maintaining the R system can be summarized as the construction of a range of functions. First, the basic functions, included in the basic installation of R. Usually, they cannot be modified by the user and even when they can be, we strongly advise against it, lest your system become unusable. Second, functions developed directly in R by any user. Many functions are made available by the community of R developers through a system of packages (more on this later).

SECTION 6.3

∗ Object oriented programming

In this section, we shall view an object as more than a quantity that can be saved and reused. We shall come closer to the spirit of the R language by looking at the internal object-oriented mechanism which governs most of its use. The incredible part is that the user does not need to worry about knowing the internal workings of R. According to us, this is a strong point of R. Nonetheless, this section should help users better understand how R proposes results. We expect this will lead to a less “random” and more controlled use of R.

6.3.1 How the internal object-oriented mechanism works

6.3.1.1 Class of an object and declaring an object

What matters in R is specifying the class of an object with the function `"class<-"()`. Recall that the function `class()` is used to check the class of an object.

5 To see this, type in the command line `apropos("<-")`.

6 The core of R is developed in the C language for obvious reasons of speed of execution, which makes it rather reactive when used in the command line.

7 To speed up execution, it is usually possible to convert an R function into C, then to call it from R via the C API.
> obj <- 1:10
> class(obj)
[1] "integer"
> class(obj) <- "MyClass"
> class(obj)
[1] "MyClass"
> class(obj) <- "OtherClass"
> obj
[1] 1 2 3 4 5 6 7 8 9 10
attr(,"class")
[1] "OtherClass"

The object obj of class integer is now an object of class OtherClass. The last display of the object obj indicates the class of the object, where attr stands for attribute. We shall come back to the notion of attributes at the end of this chapter. For now, it is enough to understand the meaning of the display attr(,"class") which is literally the “class attribute”.

That said, the above is not quite true: the object obj has kept the characteristic of also being of the integer class, as the following output shows:

> obj*2
[1] 2 4 6 8 10 12 14 16 18 20
attr(,"class")
[1] "OtherClass"

Indeed, all the elements of the vector obj have been multiplied by 2. We hope that in future versions of R, the output of the function class() applied to such an object will be similar to [1] "OtherClass" "integer", which would better show the true nature of the object.

There are two ways of knowing whether an object is of a given class:

> class(obj)=="MyClass"
[1] FALSE
> inherits(obj,"MyClass")
[1] FALSE

The function inherits() should be preferred, as we shall see when we consider polymorphic objects with several classes.

To see the class of the function function(), you can use this instruction:

> class(function() {})
6.3.1.2 Declaring objects and using methods

The mechanism for object-oriented programming is rather simple and original in R, compared to many other languages. To illustrate this mechanism, examine the most used example in R: the display of an object with the function print(). Examine the following R outputs:

```r
> vect <- 1:10
> class(vect)
[1] "integer"
> vect
[1] 1 2 3 4 5 6 7 8 9 10
> print(vect)
[1] 1 2 3 4 5 6 7 8 9 10
```

No surprises so far, although it is worth pointing out that simply entering an R object in the command line implicitly calls the function print() with the given object as effective argument. The next example confirms this: it displays an object of the class formula, characterized by the tilde symbol (\sim). In this example, we save in the variable form the formula expressing the relationship between y and x. Note that the objects y and x do not need to exist, since no evaluation is done when a formula is defined\(^8\).

```r
> form <- y \sim x
> class(form)
[1] "formula"
> form
y \sim x
> print(form)
y \sim x
```

Note that the function print() works differently for different classes of objects. For the variable form (of class "formula"), print() returned \(y \sim x\), which is the instruction to the right of the affection arrow. For the variable vect, calling print() returns \[1\] 1 2 3 4 5 6 7 8 9 10\ when we might have expected 1:10. Here is the code of the function print():

```r
> print
function (x, ...)
UseMethod("print")
<environment: namespace:base>
```

The body of this function indicates that the function UseMethod() must be executed. This function is a generic function in R. Like an airport traffic control tower, it is used to redirect the object, according to its class, to the correct function call. In the last example, this corresponds to calling the display function associated with the class formula, of the form print.formula(). In the object-oriented programming vernacular, such functions, of the general type <method>.<class>, are called methods. This explains the name of the function UseMethod() in the body of the

---

\(^8\) No further details are needed for now; we shall come back to this very original class of objects.
generic function `print()`.

Here is what happens in the backstage to simply display the object `form`:

```r
> form # Calls the function print(),
# which calls the function print.formula().
y ~ x
> print.formula(form)
y ~ x
```

Advanced users

To check how easy it is to change the general behaviour of R by changing one function, we are going to redefine the display function for the class `formula`. We are simply going to keep the standard display and add the string of characters "formula:"

```r
> print.formula <- function(obj,...)
+ cat(paste("formula:",paste(sapply(obj[c(2,1,3)],
+ as.character),collapse="")),
+ invisible(obj)
+ }
> y ~ x
formula: y ~ x
```

If you are a beginner in R, you should not try to understand the details of the R code leading to this result. Although the code seems simple, understanding it requires notions which we cannot go into in this book. Once again, the aim is rather to reveal the introspective power of R, since even its base elements can be manipulated.

To restore the initial behaviour of R for displaying formulae, you will have guessed that it suffices to delete the new function `print.formula()` with the command line instruction `rm(print.formula)`. We shall not delete it yet, because we need this behaviour later on.

If you have understood the way the function `print()` works, you might expect that there exists a function `print.integer()`. We can check this:

```r
> vect
[1] 1 2 3 4 5 6 7 8 9 10
> print.integer(vect)
Error in eval(substitute(expr), envir, enclos) :
  could not find function "print.integer"
```

The function `print.integer()` does not exist. In fact, when there is no method associated with a class, R executes the default method, which is of general form `<method>.default`; in this case, `print.default()`. Here is the output of this function for our two examples:

```r
> print.default(vect)
[1] 1 2 3 4 5 6 7 8 9 10
```
> print.default(form)
y ~ x
attr(,"class")
[1] "formula"
attr(,".Environment")
<environment: R_GlobalEnv>
> # Compare with:
> form
> formula: y ~ x

We now have a complete explanation of what happens behind the scenes. We also see that the display of a formula does not use the default method, as the last output suggests.

Tip

Also note that the function `print.default()` is used to display all base objects (or structures) of R.

In summary, to define a new family of methods, denoted here by `<method>` (name of the family of methods you wish to create), which can be applied to any type of object, you need to:

- first declare the **generic function** in the following form:
  
  ```r
  <method> <- function(obj,...) UseMethod("<method>")
  ```

- then create a **method** for a class `<class>`:
  
  ```r
  <method>.<class> <- function(obj,<list of arguments>) <body of the method>
  ```

  where `<list of arguments>` and `<body of the method>` are respectively an optional list of formal arguments and the contents of this method, which is nothing else than a function when called in its long version.

Note

Note that when declaring a family of methods, you can dissociate the name of the generic function and the argument of the function `UseMethod()` corresponding to the name of the method to call. Thus, it is easy to define an alias, called `<alias>`, of the last family of methods by simply defining a new generic function:

```r
<alias> <- function(obj,...) UseMethod("<method>")
```

As a result, the two command line calls `<method>(<object>)` and `<alias>(<object>)` for an object `<object>` of class `<class>` are equivalent to `<method>.<class>(<object>)`. A rather surprising application is that a method can be translated like this. In the next example, the French `voir` is used as an alias of `print`:

```r
> voir <- function(obj,...) UseMethod("print")
> voir(vect)
```
6.3.2 Back to the practical problem

The user realizes that he has repeated the execution of the estimations of \(a\) and \(b\) twice when creating the functions \texttt{mydisplay.reg1()} and \texttt{mysummary.reg1()} introduced in section 6.2.3 (lines 2 and 3, and lines 8 and 9). He asks advice from a more advanced user, who suggests using the concept of object-oriented programming. He proposes to create a function\(^9\) to return an object of class \texttt{reg1}, so that it can be reused thereafter as first calling argument for any method of the said class.

```r
reglin <- function(y, x) {
  aEst <- cov(x, y) / var(x)
  bEst <- mean(y) - aEst * mean(x)
  reg <- list(y = y, x = x, aEst = aEst, bEst = bEst)
  class(reg) <- "reg1"
  return(reg)
}
```

They now define the method \texttt{mydisplay.reg1()} which can be used on any object of class \texttt{reg1}.

```r
mydisplay.reg1 <- function(reg) {
  plot(reg$y, reg$x)
  abline(a = reg$bEst, b = reg$aEst)
}
```

They try a few tests.

```r
> reg <- reglin(y, x)
> mysummary(reg)
Error in eval(substitute(expr), envir, enclos) :
```

\(^9\) This kind of function is often called a constructor in object-oriented programming.
6.3 Object oriented programming

could not find function "mysummary"
> mydisplay(reg)
Error in eval(substitute(expr), envir, enclos) :
could not find function "mydisplay"

The user did not expect such errors, so he checks that the function is well defined

> mysummary.reg1(reg)
$y
[1] 1.8920106 0.3978771 -0.3970281 -0.2799578 0.7851185
[6] -0.2103208 0.1921150 -0.2647256 -0.5013911 0.6021898
$x
[1] 1 2 3 4 5 6 7 8 9 10
$aEst
[1] -0.1019453
$bEst
[1] 0.7822879
attr(,"class")
[1] "reg1"

The advanced user points out the mistake: the generic functions mysummary and mydisplay have not been declared and are not standard, unlike a few others such as print() and summary().

1 mysummary <- function(x,....) UseMethod("mysummary")
2 mydisplay <- function(x,....) UseMethod("mydisplay")

The previous instructions now work:

> mysummary(reg)
$y
[1] 1.8920106 0.3978771 -0.3970281 -0.2799578 0.7851185
[6] -0.2103208 0.1921150 -0.2647256 -0.5013911 0.6021898
$x
[1] 1 2 3 4 5 6 7 8 9 10
$aEst
[1] -0.1019453
$bEst
[1] 0.7822879
attr(,"class")
[1] "reg1"
> mydisplay(reg)

The last output produces the same plot as Figure 6.1 and is not shown here. Since the method print.reg1() has not been defined, you may wonder what would happen when we simply enter the name of the object.

> reg
$y
[1] 1.8920106 0.3978771 -0.3970281 -0.2799578 0.7851185
[6] -0.2103208 0.1921150 -0.2647256 -0.5013911 0.6021898
$x
[1] 1 2 3 4 5 6 7 8 9 10
$aEst
[1] -0.1019453
We already knew that the method `print.default()` is called in such cases.

### 6.3.3 Information about methods

To get information about methods, R has the function `methods()`:

```r
> methods("formula")  # Or more directly methods(formula).
[1] formula.character* formula.data.frame* formula.default*
[4] formula.formula* formula.glm* formula.lm*
[7] formula.nls* formula.terms*
  Non-visible functions are asterisked
> methods(class="formula")
[1] [.formula* aggregate.formula* 
[3] alias.formula* all.equal.formula 
[5] ansari.test.formula* bartlett.test.formula* 
[7] boxplot.formula* cdplot.formula* 
[9] cor.test.formula* deriv.formula 
[13] formula.formula* Friedman.test.formula* 
[15] ftable.formula* getInitial.formula* 
[17] kruskal.test.formula* lines.formula* 
[19] mood.test.formula* mosaicplot.formula* 
[21] pairs.formula* plot.formula* 
[23] points.formula* ppr.formula* 
[25] prcomp.formula* princomp.formula* 
[27] print.formula quade.test.formula* 
[29] selfStart.formula* spineplot.formula* 
[31] stripchart.formula* t.test.formula* 
[33] terms.formula update.formula 
[35] var.test.formula* wilcox.test.formula* 
  Non-visible functions are asterisked
```

Do not confuse the two uses. The first instruction outputs all methods (of the form `<method>`.`<class>`) associated with the generic function `formula`. The second instruction gives all methods for the class `formula`.

Here are a few examples to better understand the distinction between the two uses of the function `methods()`.

```r
> class(y~x)
[1] "formula"
> update(y~x, .~.+z)  # Apply the method update() to an 
# object of class formula.
```
6.3 Object oriented programming

\[
y \sim x + z
\]

```r
> update.formula
function (old, new, ...)
{
  tmp <- .Internal(update.formula(as.formula(old),
                                as.formula(new)))
  out <- formula(terms.formula(tmp, simplify = TRUE))
  return(out)
}
```

```r
<environment: namespace:stats>
> form <- "y \sim x"
> class(form)
[1] "character"
> formula(form)
y \sim x
> formula.character
Error: object "formula.character" not found
```

**Tip**

Functions followed with an asterisk can be executed, but the body of the function cannot be visualized. You can hover use the function `getAnywhere()`.

```r
> getAnywhere(formula.character)
A single object matching 'formula.character' was found
It was found in the following places
  registered S3 method for formula from namespace stats
  namespace:stats
with value
function (x, env = parent.frame(), ...)
{
  ff <- formula(eval(parse(text = x)[[1L]]))
  environment(ff) <- env
  ff
}
<environment: namespace:stats>
```

### 6.3.4 Inheriting classes

In the context of our practical problem, the advanced user informs the beginner user that R already has a set of functions to manage linear models. Indeed, the function `lm()` is dedicated to this kind of treatment (as we shall see in Chapter 12). However, he adds that to his knowledge, no functions exist to perform the specific treatment they propose. The two users work together to develop an extension; they want to avoid “reinventing the wheel” and make the most of existing functions in R.
In object-oriented programming, the notion of class inheritance seems appropriate for this kind of extension. Inheritance expresses the fact that an object of a certain class can also behave like all objects of supplementary classes. Such a mechanism is available in R, by associating a sequence of classes with an object. Thus, when a method is applied to an object which has a hierarchy of classes, the first class is solicited first. If the method exists for this class, it is executed. Otherwise, R tests whether there is an executable method in the class hierarchy. If there is, that method is executed; otherwise, the default method is executed, as long as it is defined. Finally, if none of the above apply, an execution error is generated. Let us illustrate this notion with the problem of our two users. First, we need to declare the constructor function of the new class lm1, which inherits directly from the existing class lm.

```r
lm1 <- function(...) {
  obj <- lm(...)
  if (ncol(model.frame(obj)) > 2) stop("more than one independent variable")
  class(obj) <- c("lm1", class(obj)) # Or c("lm1","lm")
  obj
}
```

Apply this to the same variables as before.

```r
> reg <- lm1(y~x)
> reg
Call: lm(formula = ..1)
Coefficients:
(Intercept)       x
 0.7823  -0.1019
```

We can see inheritance in action. No method print.lm1() is defined, and yet the object is not displayed as with print.default(). This is because R already knows the method print.lm() and the object reg inherits methods from the class lm. There are several ways of checking that this object is indeed inheriting from this class; the simplest is visualizing the contents of the class attribute with the function class(). A developer might prefer the more direct function inherits().

```r
> class(reg)
[1] "lm1" "lm"
> inherits(reg,"lm")
[1] TRUE
> print.lm(reg)
Call: lm(formula = ..1)
Coefficients:
(Intercept)       x
 0.7823  -0.1019
```

Line 4 (which we shall not comment) in function lm1() tests whether the formula is a simple regression model formula. See what happens in this next example:
We continue developing functions in the same spirit as

```r
plot.lm1 <- function(obj, ...) {
  plot(formula(obj), ...)
  abline(obj)
}
```

```r
> summary(reg)
Call:
lm(formula = ..1)
Residuals:
    Min     1Q  Median     3Q    Max
-0.8735 -0.3772 -0.2060  0.4153  1.2117
Coefficients:
              Estimate Std. Error t value Pr(>|t|)
(Intercept)  0.78229    0.48348   1.618  0.144
x           -0.10195    0.07792  -1.308  0.227

Residual standard error: 0.7077 on 8 degrees of freedom 
Multiple R-squared:  0.1763,  Adjusted R-squared:  0.07328
F-statistic: 1.712 on 1 and 8 DF,  p-value: 0.2271
> plot(reg, main="An example of simple regression")
```

In the call of `summary()` above, the method `summary.lm1()` has not been developed; hence the standard method `summary.lm()` is executed. Indeed, the object `reg` of class `lm1` then inherits from the class `lm` for all standard methods proposed by R to manage linear models. For the call of the method `plot()`, the freshly created method `plot.lm1` is invoked.
Note

Note that R has a standard method `plot.lm()` which creates a set of plots for a more detailed analysis of the results (see Chapter 12). We have intentionally changed the default behaviour of R for simple linear regression, but can still access this method by calling it explicitly (`plot.lm(reg)`).

Advanced users

Object-oriented programming is extremely simple in its conception. There are many object-oriented programming languages. An important difference is that the vast majority offer an encapsulation of object fields and methods; one of the points of this encapsulation is that the fields of an object can be modified within a method. This is not directly possible in R because of the strict local scope of variables inside the code of an R function. The users can however adopt this kind of programming if they want to. Any method `<method>.<class>()` which needs to modify the fields of an object `<object>` (of class `<class>`) must then return the object itself. The user of the generic function `<method>()` can then affect the result to the initial object, as follows:

```
<object> <- <method>(<object>). However, this risks to slow down execution, all the more if the contents of the object fields are large. This is because the object is completely duplicated. We hope that R developers will one day offer a more elegant standard functionality (analogous to what the majority of object-oriented programming languages offer), whereby only the relevant fields (of which there are usually few) are modified inside the body of the method. When you become an advanced user (as we hope), you will notice that the notion of pointers (which is very common in programming) is not directly offered to R developers (see however the function `tracemem()` as well as 7.8.2.2, page 294).
```

SECTION 6.4

† Going further in R programming

Before you start programming in a language, it is good to know the spirit in which it was conceived. In this section, we shall explore structures of the R language which you do not need to know when you start using R, but which you will find very useful when you decide to go deeper in your use of R. These elements make R an original and powerful tool. We advise beginner users to skim through this section without trying to master the concepts. All the information in this section is second-level, in the sense that a very powerful use of R is possible without it.
6.4 Going further in R programming

6.4.1 R attributes

An R object includes primary information, conveyed by the basic structures presented in this book. There is another level of information, which we call secondary information. It is attached to an object with attributes and can be accessed with the function `attributes()`.

```r
> mat <- matrix(1:10, nrow=2)
> mat
[1,]  1  3  5  7  9
[2,]  2  4  6  8 10
> class(mat)
[1] "matrix"
> attributes(mat)
$dim
[1] 2 5
```

We shall comment on this output later. For now, let us insist again on the fact that this mechanism is supposed to be transparent for the user, who usually cares more about the contents of the R object. For day-to-day use, we advise you not to change attributes directly. This stand is justified by the existence of many functions to manipulate attributes indirectly. However, a developer who wishes to learn more about the internal workings of R will discover a few supplementary characteristics which usually enlighten the behaviour of the object. We have already indirectly manipulated the attribute class with the functions `class()` and "class<-"(). We shall also manipulate the three other main attributes: dim, names and dimnames. These are used a lot in the internal management of R. The next example is only interesting to present how to handle attributes. The complementary function `attr()` is used to manipulate a single attribute at a time, whereas the function `attributes()` returns all attributes as an R list.

```r
> vect <- 1:10
> attr(vect,"test") # Returns NULL, because vect has no attribute test.
NULL
> attributes(vect) # NULL because vect has no attributes.
NULL
> # Affecting an attribute "attrib1" containing the character string "TEST1".
> attr(vect,"attrib1") <- "TEST1"
> attr(vect,"attrib1")
[1] "TEST1"
> # Affecting an attribute "attrib2" containing the vector c(1,3)
> attributes(vect)$attrib2 <- c(1,3)
> attributes(vect)$attrib1
[1] "TEST1"
$attrib2
[1] 1 3
> attr(vect,"attrib2")
```
> # Modifying attribute "attrib1" and deleting attribute "attrib2"
> attributes(vect)$attrib1 <- 3:1
> attr(vect,"attrib2") <- NULL
> attributes(vect)
$attrib1
[1] 3 2 1
> # Deleting all attributes at once
> attributes(vect) <- NULL
> attributes(vect)
NULL

The attribute access mechanism is simple to use. This example has shown how to change attributes using the functions "attr<-()" and "attributes<-()". The value of an attribute can be any R object. Affecting NULL to an attribute deletes it.

### 6.4.1.1 Attribute class

In the previous section on object-oriented programming, we have manipulated the attribute class using the functions class() and "class<->()". This shows that you do not need to know how to manipulate attributes directly. We return to the example we used, to show that manipulating this attribute is equivalent to using the utility functions class() and "class<-()".

> form <- y~x
> attributes(form)
$class
[1] "formula"
$.Environment
<environment: R_GlobalEnv>
> class(form)
[1] "formula"
> obj <- 1:10
> attr(obj,"class") # No class attribute.
NULL
> class(obj) # And yet!
[1] "integer"
> attr(obj,"class") <- "MyClass" # Equivalent to class(obj) <- "MyClass".
> class(obj)
[1] "MyClass"

There is nothing left to say about this attribute, even though it plays a central role in object-oriented programming in R.

### 6.4.1.2 Attribute dim

The attribute dim plays an important role in the behaviour of matrix and array objects. Here is an example with a matrix:
> mat <- matrix(1:12, nrow=2)
> mat
[1,]  1  3  5  7  9 11
[2,]  2  4  6  8 10 12
> attr(mat,"dim")
[1] 2 6
> attributes(mat)
$dim
[1] 2 6
> attr(mat,"dim") <- c(3,4)  # Changing shape: 3 rows and 4 columns.
> mat
[1,]  1  4  7 10
[2,]  2  5  8 11
[3,]  3  6  9 12
> attributes(mat)$dim <- c(2,6)  # Back to the initial shape.
> mat
[1,]  1  3  5  7  9 11
[2,]  2  4  6  8 10 12

In this example, changing the attribute dim allowed us to change the shape of the matrix. We have already mentioned that attribute management is meant to be transparent for the user, so you might expect there to exist similar functions with more user-friendly names. For this example, we could have used the functions dim() and "dim<-":

> dim(mat)
[1] 2 6
> dim(mat) <- c(1,12)  # Changing shape: 1 row and 12 columns.
> mat
[1,]  1  2  3  4  5  6  7  8  9  10  11  12
> dim(mat) <- c(2,6)  # Back to the initial shape.

To really understand how R represents objects such as matrices and arrays, let us analyse the following output:

> mat
[1,]  1  3  5  7  9 11
[2,]  2  4  6  8 10 12
> class(mat)
[1] "matrix"
> dim(mat) <- NULL  # Or attributes(mat)$dim<-NULL or attributes(mat) <- NULL.
> mat
[1,]  1  2  3  4  5  6
[2,]  7  8  9 10 11 12
> is.vector(mat)
[1] TRUE
> class(mat)
[1] "integer"
> dim(mat) <- c(2,2,3)
> mat
[ ,1] [ ,2]
[1, ] 1 3
[2, ] 2 4
[ ,2] [ ,2]
[1, ] 5 7
[2, ] 6 8
[ ,3] [ ,2]
[1, ] 9 11
[2, ] 10 12
> is.vector(mat)
[1] FALSE
> class(mat)
[1] "array"

When we delete the attribute `dim`, the object `mat` becomes a simple vector. When we affect a vector of three integers to this attribute, the object `mat` becomes an array of dimension 3. The different behaviours of vectors, matrices and arrays thus stem from the value of the attribute `dim`.

Warning

Although the display is the same, a vector and a single-index array are treated differently by R, as shown by these few lines of code:

> dim(mat) <- 12
> mat
[1] 1 2 3 4 5 6 7 8 9 10 11 12
> is.vector(mat)
[1] FALSE
> class(mat)
[1] "array"
> identical(mat,1:12)
[1] FALSE
> dim(mat) <- NULL
> mat
[1] 1 2 3 4 5 6 7 8 9 10 11 12
> is.vector(mat)
[1] TRUE
> class(mat)
[1] "integer"
> identical(mat,1:12)
[1] TRUE

It looks like we have said everything about the attribute `dim`, but there is one last application worth noting. The only difference between a vector and a list is that
the elements of a vector must all have the same type. Matrices and arrays usually contain elements of the same nature as well; this constraint is very important for matrix operations. But as storage structures, you could imagine extending the matrix and array concepts to lists, by affecting the `dim` attribute, as is done with vectors. The documentation files for the `matrix()` and `array()` instructions show that this is the case, since the first calling argument of these functions can be a list instead of a vector. The next example applies this to a matrix; the same could be done with an array, as long as the number of elements in the list agrees with the dimension.

```r
> lmat <- matrix(list(7,1:2,1:3,1:4,1:5,1:6),nrow=2)
> lmat    # Returns the structure and not the contents, which
    # are too difficult to display.
  [,1]   [,2]    [,3]
 [1,] 7 Integer,3 Integer,5
 [2,] Integer,2 Integer,4 Integer,6
> dim(lmat)
[1] 2 3
> is.list(lmat)
[1] TRUE
> lmat[1,2] # Extract the element at row 1 and column 2.
[1] 1 2 3
> lmat[,-2] # Extract the submatrix with the second column
    # removed.
  [,1]   [,2]
 [1,] 7 Integer,5
 [2,] Integer,2 Integer,6
> dim(lmat) <- NULL
> lmat    # This is just a list now.
 [1]
 [1] 7
 [2]
 [1] 1 2 3
 [3]
 [1] 1 2 3
 [4]
 [1] 1 2 3 4
 [5]
 [1] 1 2 3 4 5
 [6]
 [1] 1 2 3 4 5 6
> is.list(lmat)
[1] TRUE
```

The attribute `names` plays an important role in naming elements of a list.

```r
> li <- list(1:3,letters[1:3])
> li

[[1]]
[1] 1 2 3
```

### 6.4.1.3 Attributes names and dimnames

The attribute `names` plays an important role in naming elements of a list.
The first and fourth instructions are thus equivalent to the following, more common declaration:

```r
> li <- list(numbers=1:3,letters=letters[1:3])
```

It is a less useful and lesser known fact that this attribute can also be used on any type of vector.

```r
> vect <- 1:3
> attr(vect,"names") <- letters[1:3]
> vect
```

```r
a b c
1 2 3
```

```r
# Or directly
> vect2 <- c(a=1,b=2,c=3)
> vect2
```

```r
a b c
1 2 3
```

You do not need to manipulate the attribute `names` directly. Accessing and changing its value can be done explicitly:

```r
> names(li)
[1] "numbers" "letters"
> names(li) <- c("num","lett")
> li
$num
[1] 1 2 3
$lett
[1] "a" "b" "c"
> names(vect)
[1] "a" "b" "c"
> names(vect) <- toupper(names(vect))
> vect
A B C
1 2 3
```

For objects with several indices, such as matrices and arrays, index name management is done internally by modifying the attribute `dimnames`, as shown in this quick example.

```r
> mat <- matrix(1:6,nr=2)
> mat
[,1] [,2] [,3]
[1,] 1 3 5
```

```r
> mat$dimnames <- list(1:2,1:3)
> mat
```
> attributes(mat) # Can be modified as an attribute.
$dim
[1] 2 3
> rownames(mat) # Row names.
NULL
> colnames(mat) # Column names.
NULL
> dimnames(mat) # Row and column names as a list.
NULL
> colnames(mat) <- paste("V","1:3",sep="")
> rownames(mat) <- c("a","b")
> mat
   V1 V2 V3
a  1  3  5
b  2  4  6

For an array with more than two dimensions, the functions rownames and colnames are meaningless. You can either modify the attribute dimnames directly, or use the function "dimnames<-"() .

---

Note

Data frames have a special status. They are defined as lists and are usually manipulated as matrices. The attributes for row and column names are row.names and names (instead of col.names):

> df <- data.frame(a=1,b=1:2)
> df
   a b
 1 1 1
 2 1 2
> attributes(df)
$names
 [1] "a" "b"
$row.names
 [1] 1 2
$class
 [1] "data.frame"
> names(df) # As a list.
 [1] "a" "b"
> dimnames(df) # As an array: list of two vectors.
[[1]]
 [1] "a" "b"
[[2]]
 [1] "1" "2"
> rownames(df) # As a matrix: accessing the row names.
 [1] "1" "2"
> colnames(df) # As a matrix: accessing the column names.
 [1] "a" "b"
The last four lines give calls to access these attributes without manipulating them directly. Corresponding forms exist to change their values. Note that the attribute class gives the class of the object.

### 6.4.2 Other R objects

It could be said that one of the specificities of R is that the vast majority of quantities manipulated by R are allocated to variables and can thus be reused later on. There are a few exceptions, mostly control structures. R objects are of different types, called classes. We have already encountered object classes used to store common data. There are three other object types we chose to explore as well. Surprisingly, formulae and environments are also objects in R; we shall also introduce R expressions, which are objects in which R code can be stored to be executed at a later time.

#### 6.4.2.1 R expressions

So far, we have said nothing on structures used to described the syntactic bases of R. Following its philosophy of managing as many components as possible, R can manipulate an R expression and split it into a sequence of atomic entities (such as call, name...). We only mention these capacities, without going into the details. We shall focus on R expressions which are truly of interest to an R developer. It is difficult to give a rigorous definition of R expressions. We propose the following definition, inspired by command line use of R. An R expression can be seen as R code entered in sequence as command lines until it is executed by the R interpreter. (i.e. until the character > is displayed, inviting a new command). This expression can spread over several lines. The function expression() is used to declare an R expression when it is used with a single calling argument. It is however possible to give a sequence of expressions, each expression corresponding to one effective argument in the call of a function. An expression object is not evaluated by the R interpreter but can be saved to be evaluated later, as many times as needed. Evaluating an R expression is done with the function eval(). All of this is illustrated in this example:

```
> expression(v<-'value')  # The expression v<-'value'
expression(v <- "value")  # is not evaluated.
> v
Error in eval(substitute(expr), envir, enclos) : object 'v' not found
> expression(v<-'value') -> expr  # Saved in the object expr.
> expr
expression(v <- "value")
> eval(expr)  # Evaluating expr.
> v
> # Here is the expected result.
```
6.4 Going further in R programming

A developer will find it useful to convert a character string describing R code into an R expression to be evaluated at another time. The function `parse()` is used to this effect:

```r
> parse(text='v<"value"') -> expr
> expr
expression(v <- "value")
> attr(expr,"srcfile")
<text>
> eval(expr)
> v
[1] "value"
```

The formal argument `text` is used here to read a character string, but the first use of the function is to read a file containing R code; the name of the file is given as the first effective argument.

### Tip

Here is an example using the functions `eval()` and `parse()`:

```r
> for (i in 1:3) eval(parse(text=paste("a",i," <- i",sep="")))
> a2
[1] 2
```

We are now going to manipulate the function `expression()` to describe some of the internal behaviour of R. This will help understand why R is said to be a functional language (i.e. which makes an intensive use of functions). It is surprising how true this is. This first point shows that upon execution, affectation is considered as an operator (a function with two arguments). The first argument corresponds to the variable, the second to the contents.

```r
> foo <- "foo"
> foo
[1] "foo"
> "<-"(foo,"foo2")                      # Equivalent to: foo <- "foo2"
> foo
[1] "foo2"
> expression("<-"(foo,"foo2"))         # as shown by the output of this
expression.
expression(foo <- "foo2")
```
We continue our exploration with brackets. One of the uses of brackets is to order execution priorities in an R expression. Again, R treats them as a function.

```r
> 30*(10+20)
[1] 900
> 30+"(10+20)" # This is what is executed behind the scenes.
[1] 900
> expression(30*(10+20))
expression(30 + (10 + 20))
> expression(30+"(10+20))
expression(30 + (10 + 20))
```

The same is true for the notion of expression blocks. An expression block is defined as a sequence of R expressions, grouped between curly bracket delimiters "{" and "}".

```r
> { + print("line1") + print("line2") + }
[1] "line1"
[1] "line2"
> "{print("line1"),print("line2")}
[1] "line1"
[1] "line2"
> expression({ + print("line1") # This comment is not interpreted. + + # Neither is this comment. + print("line2") + })
expression({
  print("line1")
  print("line2")
})
> expression( "{print("line1"),print("line2")} 
expression({
  print("line1")
  print("line2")
})
```

Note that comments and spaces are ignored by the R interpreter. When we describe the syntax of R instructions, we shall follow the convention of denoting R expressions by <expr...> (where ... can be any string of characters). Note that to make your code easier to read, you can add as many carriage returns as you wish in a block without any effect on its execution.

### 6.4.2.2 R formulae

The formula object is one of the specificities of R. It is mainly used to establish a relationship between two parts, separated with a tilde ~. Both parts must be R ex-
expressions. Keeping in mind what we have learnt about the function `expression()`, we can see how R converts a formula into a "∼" function upon execution.

```r
> y ~ x
y ~ x
> "~"(y,x)     # Equivalent expression,
y ~ x
> expression("~"(y,x)) # as this expression proves.
expression(y ~ x)
```

For developers, expressions can be used to offer a more user-friendly interface, since they are closer to the usual form. For example, the R formula `y~x` can express that `y` and `x` are linked, or that `y` is a function of `x`. Generally speaking, the developer bears the responsibility of interpreting the formula to perform the necessary tasks. This is very advanced; we refer the interested reader to the R documentation files.

Here are a few examples with no particular meaning, but which will help become familiar with this new object:

```r
> y ~ x
y ~ x
> y ~ (x + y:z) * t | v
y ~ (x + y:z) * t | v
> y1 + y2 | w ~ (x + y:z) * t | v
y1 + y2 | w ~ (x + y:z) * t | v
```

It is worth pointing out that even if the quantities mentioned in the formulae above are not existing R objects, no error is thrown. However, remember that a syntax error results in an error message:

```r
> y ~ x+y) * t | v
Error: ')' not expected in "y~x+y"
```

We now focus on usage of formulae in the R system. Since formulae are not common objects, the user may not realize that they are saved like any other R object.

```r
> form <- y ~ x
> form
y ~ x
```

The two main uses are for plots and for statistics.

For plots, this is an alternative to what we introduced in Chapter 5.

```r
> x <- runif(10)
> y <- runif(10)
> plot(x,y)
> plot(y ~ x)
```

The resulting plot is not shown here, since the only interest is in showing that the instructions with or without the formula are equivalent. Note that the variables `x` and `y` are inverted between the two forms. The version with the formula `plot(y ~ x)` expresses more literally the action we want: plot `y` as a function of `x`. This version, which we find elegant, is of course also available for the complementary functions `points()` and `lines()`.
In a statistical context, a function relative to the specific treatment of a statistical model takes as input argument a formula establishing the relationship between the variables of the model (the formula is often the first argument). The most simple example is the linear model; here is an example:\(^{10}\):

```r
> lm(y~x)  # x and y must be defined (and they are in this case!)
Call:
lm(formula = y ~ x)
Coefficients:
(Intercept)     x
 0.46290  -0.06904
```

Besides the pleasant syntax, the formula object also offers a very efficient interface with the user to describe the model. This is confirmed by the fact that, unlike for plots, there is no other way of describing the relationship between the variables in the model. You might think that the syntax `lm(y,x)` could have been used. But then how would you write as a list of input arguments the formula `y\sim(x+z)^*t`, which is perfectly valid (see Chapter 13)?

For operations on formulae, you can use the function `update()` which modifies a formula, using another one.

```r
> update(y~x,.~+z)  # Change y~x into y~x+z.
y ~ x + z
> form <- y~x      # The same procedure with a saved model.
> form2 <- update(form,.~+z)
> form2
y ~ x + z
> update(form2,.~-.x)  # You can also delete a variable.
y ~ z
```

These examples show the syntax of the function `update()`. The first formal argument is the formula you wish to modify; the second formal argument gives the operations to perform on the formula, using a specific syntax. All that remains to be done is to analyse the syntax of the second formula. Any dot "." before the tilde character \( \sim \) is replaced with the left expression of the initial formula (before the tilde). Similarly, any dot "." after the tilde is replaced with the right expression of the initial formula (after the tilde).

\(^{10}\) This section does not give details on handling linear models in R; this will be the focus of Chapter 12.
6.4.2.3 The R environment

The notion of environment is necessary in any programming language. It can be seen
as a storage space of R objects. When you open your R session, a first environment
.GlobalEnv is created by R. It is called the workspace and all objects manipulated
with the command line during this session are stored there. Although we only wish
to give an overview of this concept, it is worth mentioning that the notion of func-
tion depends intrinsically on the notion of environment. Here is a glimpse of this
fact. When you create a new object in the body of a function, R takes care of declar-
ing it internally in an environment specific to this function, to store the contents of
the object. The reason for this is that if the object has the same name as an object
of the environment .GlobalEnv, this last object will not be overwritten with the
value defined in the body of the function. To better understand what an environment
is, note that the value of an object defined in the environment .GlobalEnv can be
accessed in the body of the function. However, its value cannot be modified by an
affectation with the same object name. The reason why you can access an object
which was defined in another environment than the one associated with the function
is that a parent environment is specified when declaring a new environment. It is al-
lowed that an environment have no parent, as is the case with the initial environment
.GlobalEnv. When an object is not directly available in the environment of a func-
tion, R searches for the object in the parent environment. If it is still not available,
there are two possibilities: either there exists a “grandparent” environment, and the
search continues, or there is no such environment and an error is thrown indicating
that the object could not be found. This exploration process is repeated recursively
until the object is found. Most environment declarations are done internally and in-
visibly by R. We shall return to this notion when we give more details on developing
functions. A very surprising feature is that an environment is considered as an R ob-
ject. A new environment can thus be declared to execute a specific block of code
without changing the workspace .GlobalEnv. The function local(), which takes
as first argument the code to execute and as second argument the environment for
the execution, is very useful to this end:

```r
> a <- 12; b <- 13
> space <- new.env() # By default, the parent is the environment
                  # from which new.env is called.
> local({
      + a <- b+2
      + a
    }, space)
[1] 15
> a # The value of a has not changed in .GlobalEnv.
[1] 12
> space$a # Value of a in the environment space.
[1] 15
```

The function’s name is well chosen: the value of a in the workspace .GlobalEnv
has been preserved. As stated in the comment, the parent of space (generated by
new.env() is \( \texttt{GlobalEnv} \), but the parent could have been specified by giving a value to the formal argument \texttt{parent}. Here are two examples of parent declaration:

```r
> space2 <- new.env(parent=emptyenv())
> local(a<-b+2,space2) # Error!!!
Error in eval(expr, envir, enclos) : could not find function "<-"
> space2$a # Unsurprisingly, the object \( a \) does not exist!

NULL
```

The environment \( \texttt{space2} \) is useless, since its parent environment is an empty environment \( \text{\it i.e.} \) no parent; declared with the function \texttt{emptyenv()}). The execution error in the local code is because even the affectation function \( \texttt{<-} \) cannot be accessed: the empty environment knows absolutely nothing about \texttt{R}; in particular, it does not know the basic functions. The function \texttt{globalenv()} returns the global environment \( \texttt{GlobalEnv} \) which is always first in the access list of \texttt{R} environments.

```r
> space3 <- new.env(parent=parent.env(globalenv()))
> local(a<-b+2,space3) # Error, because \texttt{GlobalEnv} cannot be accessed!
Error in eval(expr, envir, enclos) : object 'b' not found
> local(a<-15,space3)
> a

[1] 15
> space3$a

[1] 15
```

Environments are rather convenient: they are used like a list.

```r
> space3$b <- b-1
> b

[1] 13
> space3$b

[1] 12
```

For further details, we refer the reader to the online help, which is rather complete, but aimed at advanced users.

---

**SECTION 6.5 † Interfacing \texttt{R} and \texttt{C/C++} or \texttt{Fortran}**

You may be wondering why you should consider writing parts of your code in \texttt{C/C++} or \texttt{Fortran}. There are several reasons, such as:

- to use from \texttt{R} a pre-existing routine, formerly coded in \texttt{C/C++} or \texttt{Fortran};
- to speed up the runtime of your \texttt{R} code;
- to use the graphical capabilities of \texttt{R} or some \texttt{R} functions on numerical output from \texttt{C/C++} or \texttt{Fortran} code.
6.5 Interfacing R and C/C++ or Fortran

Tip

The last version of R includes a byte compiler which speeds up some computations. You can also use the R version distributed by the company Revolution Analytics (http://www.revolutionanalytics.com). It has been optimized to speed up some computations, for example by relying on a multi-core architecture when available.

See also

We assume that the reader already has some notions of C/C++ and/or Fortran programming. If that is not the case, the books [22] and [38] for C and C++, and [9] for Fortran may be of use.

In this section, we do not claim exhaustivity. We shall only present a few simple examples which illustrate the points made above. Along the way, we shall provide some basics which we hope will allow you to get by on your own afterwards.

Warning

Before you start, you need to install C/C++ and Fortran compilers, since Microsoft Windows does not have any by default. The free software Rtools, containing several tools from the Linux world, has been created to this end. You can download it from http://cran.r-project.org/bin/windows/Rtools. Choose Full installation to build 32 or 64 bit R 2.14.2+ if you have a 64 bit processor. Tick the appropriate box when installing Rtools, so that the variable PATH is correctly configured. You also need to change the system environment variable Path so that it contains the path to the R installation folder (one way to find the path is to right-click on the R icon of the Desktop, then choose properties). This will allow you to call R from an MS-DOS command window, as we shall mention later on. To do this, right-click on the Windows Desktop, select New/Shortcut, then enter the following instruction in the window that opens: control.exe sysdm.cpl, System, 3

Once this shortcut has been created on the Desktop, double-click on it, and in the window that opens, click on Environment Variables... Change the value on the system variable Path to add at the beginning (using ; as separator) the path to the folder containing the R executable (which should look like C:\Program Files\R\R-2.15.1\bin\i386 or C:\Program Files\R\R-2.15.1\bin\x64) and the path to the folders of Rtools (which should look like C:\Rtools\bin and C:\Rtools\gcc-4.6.3\bin), if they are not already present.
6.5.1 Creating and running a C/C++ or Fortran function

The next example shows how to speed up a program by using C/C++ or Fortran. The R function `combn()` is able to handle all combinations of a given number of elements taken from a given vector. For example, this instruction generates all combinations of size 3 from the vector 1:5.

```r
> combn(5, 3)
[1,]  1  1  1  1  1  1  2  2  3
[2,]  2  2  2  3  3  4  3  4  4
[3,]  3  4  5  4  5  5  4  5  5
```

If we attempt to get all \( \text{choose}(n, m) \) combinations (for example 1,313,400 combinations if \( n = 200 \) and \( m = 3 \)) from a vector of larger size \( n \), the computation time can increase drastically.

```r
> system.time(x <- combn(200, 3))
user  system elapsed
14.959  0.227  15.188
```

The command `system.time()` shows that the above computation takes several seconds on the computer used to write this book (if your computer is faster, take a value greater than 200).

Tip

The function `permn()` of package `combinat` can be used to generate all permutations of the elements of a vector.

A simplified version of the original R function `combn()` is given below:

```r
> combinR <- function(n, m) {
+   a <- 1:m; e <- 0; h <- m
+   combmat <- matrix(0, nrow=m, ncol=choose(n, m))
+   combmat[,1] <- 1:m
+   i <- 2
+   nmmp1 <- n - m + 1
+   mpl1 <- m + 1
+   while (a[1] != nmmp1) {
+     if (e < n-h) {
+       h <- 1; e <- a[m]; a[m-h+1] <- e + 1
+       combmat[,i] <- a
+       i <- i + 1
+     } else {
+       h <- h + 1; e <- a[mpl-h]
+       a[(m-h+1):m] <- e + 1:h
+       combmat[,i] <- a
+       i <- i + 1
+     }
+     return(combmat)
+   }
+ }
```
We now propose two functions coded in C/C++, and another two coded in Fortran, to make the same computation in much shorter time.

- Creating the C/C++ function.

C++ code for function combnC, downloadable from http://biostatisticien.eu/springeR/combn.cpp:

```cpp
#include <math.h>

void combnC(int *combn, int *n, int *m) {
    int i, j, e, h, nmmp1, mpl;
    int *a;
    a = new int[m[0]];
    for (i = 1; i <= m[0]; i++) a[i-1] = i;
    e = 0;
    h = m[0];
    for (i = 1; i <= *(m+0); i++) combn[i-1] = i;
    i = 2;
    nmmp1 = n[0] - m[0] + 1;
    mpl = m[0] + 1;
    while (a[0] != nmmp1) {
        if (e < n[0] - h) {
            h = 1;
            e = a[m[0] - 1];
            a[m[0] - h] = e + 1;
            for (j = 1; j <= m[0]; j++) combn[(i-1)*m[0]+j-1] = a[j-1];
            i = i + 1;
        } else {
            h = h + 1;
            e = a[mpl - h-1];
            for (j = 1; j <= h; j++) a[m[0] - h + j-1] = e + j;
            for (j = 1; j <= m[0]; j++) combn[(i-1)*m[0]+j-1] = a[j-1];
            i = i + 1;
        }
    }
    delete[] a;
}
```

Code for the main function, downloadable from http://biostatisticien.eu/springeR/main.cpp:

```cpp
#include <iostream>

using namespace std;

extern "C" { extern void combnC(int *combn, int *n, int *m); }
```
6 Programming in R

```c
int *n, *m, *combmat, j;
double Cnm;
n=new int[1];
m=new int[1];
n[0]=5;
m[0]=3;
Cnm=10;
combmat=new int[(int)Cnm*m[0]];
combnC(combmat, n, m);
for (j=1; j<=Cnm*m[0]; j++) cout << combmat[j-1] << " ";
```

Note that all indices start at zero in C/C++, unlike R where they start at 1.

- Creating the Fortran function.

Fortran code for the subroutine `combnF`, downloadable from http://biostatisticien.eu/springerR/combn.f90:

```fortran
SUBROUTINE combnF(combmat, n, m)
  integer, intent(in) :: n,m
  integer :: i,j,e,h,nmmp1,mp1
  integer, dimension(m) :: a
  integer, dimension(*) , intent(out)::combmat
  do i=1,m
    a(i)=i
  end do
  e=0
  h=m
  do i=1,m
    combmat(i)=i
  end do
  i=2
  nmmp1=n-m+1
  mp1=m+1
  do while (a(1).ne. nmmp1)
    if (e < n-h) then
      h=1
      e=a(m)
    end do
    a(m-h+1)=e+1
    do j=1,m
      combmat((i-1)*m+j)=a(j)
    end do
    i=i+1
  end do
```
else
h=h+1
e=a(mpl−h)
do 40 j=1,h
a(m−h+j)=e+j
40 continue
do j=1,m
combmat(((i−1)*m+j)=a(j)
end do
i=i+1
endif
enddo
END SUBROUTINE combnF

Code for the main function, downloadable from http://biostatisticien.eu/springeR/main.f90:

1 PROGRAM main
2 integer :: n,m,Cnm,j,k
3 integer, allocatable, dimension(:) :: combmat
4 n=5
5 m=3
6 Cnm=10
7 k=Cnm*m
8 allocate(combmat(k))
9 CALL combnF(combmat,n,m)
10 write(*,*)(combmat(j),j=1,k)
11 deallocate(combmat)
12 end PROGRAM main

* Compiling and running the C/C++ or Fortran function.

In order to use the C++ or Fortran code given above, it needs to be compiled, i.e. transformed into an executable file. To do this, simply open an MS-DOS terminal window, for example from the Windows menu Start/Run (or with the keyboard combination [WINDOWS]+R) and type the instruction cmd followed by ENTER. In this black window, type the two instructions below.

Warning
You may need to move to the directory where your files were saved, using the MS-DOS command cd (for change directory). For example, if you created your files on the Windows Desktop, use:

cd Desktop
Note that under MS-DOS, the command `dir` is used to list the contents of the current directory.

:: To compile C/C++ code:
g++ -o mycombn.exe combn.cpp main.cpp
:: To compile Fortran code:
gfortran -o mycombn.exe combn.f90 main.f90
:: To run the function:
mycombn.exe

The first instruction compiles our C++ or Fortran code to produce the executable file `mycombn.exe`. The second instruction launches this executable file and displays, though with no formatting, the result of the computation.

Tip

The function `system()` is used to execute a DOS command outside of R. For example, in R, type:

```
> system("mycombn.exe")
```

Note that you must of course first change the current R directory, using function `setwd()` for example, to change to the directory containing the file `mycombn.exe`.

Tip

The compilation flag `-Wall` is used to display all compilation warnings or errors (if there are any!):

```
g++ -o mycombn.exe combn.cpp main.cpp -Wall
```

We shall now produce the \( \binom{200}{3} = 1313400 \) sub-vectors made of all possible combinations of three elements in vector `1:200`. For the C/C++ version, modify lines 11, 13 and 16 of the code of function `main` given page 231. These lines become:
6.5 Interfacing R and C/C++ or Fortran

\[ n[0] = 200; \]
\[ \text{Cnm} = 1313400; \]
\[ \text{// for (j=1; j<=Cnm*m[0]; j++) cout << combmat[j-1] << " ";} \]

For the Fortran version, modify lines 4, 6 and 10 of the code of function main given page 233. These lines become:

\[ n = 200 \]
\[ \text{Cnm} = 1313400 \]
\[ \text{!write(*,*) (combmat(j) ,j=1,k)} \]

We commented out the last line (using // in C/C++ and ! in Fortran) so that a call of mycombn.exe no longer displays the (now very large) result of the computation, which would take a lot of time. But the calculation is made. We thus coherent with the previous computation done in R, for which the result was not displayed but stored in variable \( x \). After saving your changes, recompile and run your code:

:: To compile C/C++ code:
\[ g++ -o mycombn.exe combn.cpp main.cpp \]
:: To compile Fortran code:
\[ gfortran -o mycombn.exe combn.f90 main.f90 \]
:: Execute the function:
\[ mycombn.exe \]

You can see that the calculation (without displaying the result) is done very quickly.

6.5.2 Calling C/C++ (or Fortran) from R

We shall now see how to call the C++ code from file combn.cpp (or rather a compiled version of this code) directly from R, without using a main function. To this end, we create an R wrapper containing a call of the C++ function.

Note

R can only call C/C++ or Fortran functions which do not return any output. All C/C++ functions must thus be of type \texttt{void} and all Fortran routines must be subroutines. The results will go in the arguments of the calling function.

Download the file \texttt{http://biostatisticien.eu/springeR/combn.R}, which includes the code given below:

```
1  combnRC <- function(n,m) {
2    combmat <- matrix(0, nrow=m, ncol=choose(n,m))
3    lib <- paste("combn", .Platform$dynlib.ext, sep="")
4    dyn.load(lib)
5    out <- .C("combnC", res=as.integer(compmat),
```
as.integer(n), as.integer(m))
combmat <- matrix(out$res, nrow=m, byrow=F)
dyn.unload(lib)
return(combmat)
}

Note
To call the Fortran code, replace line 5 by
out <- .Fortran("combnF", res=as.integer(combmat),

The functions dyn.load() and dyn.unload() allow respectively to load and unload from R's memory the resources from a DLL (Dynamic Link Library) file. A DLL includes functions which can be called during the execution of a program, without being included in its executable. Here, it is the file combn.dll (which includes only one function), which will be created further on.

The functions .C() and .Fortran() (which output a list) are used to send values from R to a C/C++ or Fortran function respectively. Use the instructions as.integer(), as.double() or as.character() in R to declare objects made of integer values, decimal (numeric) values, or character strings, so that they are "received" correctly by the arguments of the C/C++ or Fortran function.

For a C/C++ function, all arguments must be pointers; for example integer pointers (int *), real pointers (double *) or character pointer pointers (char **). Table 6.1 gives the equivalent types in R, C/C++ and Fortran.

Table 6.1: Conventions on argument types. Type ?.Fortran for further detail.

<table>

</tbody>
</table>
Interfacing R and C/C++ or Fortran

Warning

Unlike R, where it is very easy to get the length of vector x with the instruction `\texttt{length(x)}`, in C/C++ it is not possible to know the length of x. It can sometimes be useful to give to the function \texttt{.C()} both the vector x and its length, for example as follows for some hypothetical function \texttt{functionC}:

\begin{verbatim}
  x <- c(1.2, 0.7, 3, 2, 4, 1, 0.9)
  .C("functionC", as.double(x), as.integer(length(x)))
\end{verbatim}

The arguments of the C/C++ function \texttt{functionC} are: \texttt{double *x} and \texttt{int *n}. The same remark applies to Fortran functions.

Note

The C/C++ function \texttt{combnC} returns \texttt{void}: it does not have any direct output. However, the value of its arguments, which are pointers, can be modified during execution. It is then possible to access directly (thanks to their address) to the value of these pointers. This is how R works, using the function \texttt{.C()} (in a transparent way for the user).

You may have noted at line 5 of the code of function \texttt{combnRC()} above, that we used \texttt{res=} when calling function \texttt{.C()}. This allows us to use \texttt{out$\texttt{res}} directly, instead of \texttt{out[[1]]}. You can use another name than \texttt{res}, and for any argument of function \texttt{.C()}. For example, we could have used \texttt{val=as.integer(m)}, which we did not do because that value was not modified by \texttt{combnC}, and is thus already known (as \texttt{m}). A similar remark applies to Fortran functions.

We shall now create the file \texttt{combn.dll}, which will be called by R. To this end, type the following instructions in an MS-DOS window:

\begin{verbatim}
:: In C/C++:
  g++ -c combn.cpp -o combn.o
  g++ -shared -o combn.dll combn.o
:: In Fortran:
  gfortran -c combn.f90 -o combn.o
  g++ -shared -o combn.dll combn.o
\end{verbatim}

Tip

Equivalently (or almost equivalently, since optimization arguments could be used by the compiler, which might by the way hinder debugging), this dynamical library could be created (after deleting if necessary the files \texttt{combn.o} and \texttt{combn.dll}) with one instruction:

\begin{verbatim}
  R CMD SHLIB combn.cpp -o combn.dll
\end{verbatim}
The first instruction creates the object file `combn.o`, which contains the machine code for the function included in file `combn.cpp`. The second instruction creates the dynamic library `combn.dll`. At this step, the compiler informs us of any errors to correct in the program (with the corresponding line number).

**Tip**

Note that it is possible to include several object files in the same library, which will then contain several functions. For example, if we had a file `choose.o` containing the machine code for a function which calculates binomial coefficients, we could include both functions in a DLL as follows:

```
g++ -shared -o combn.dll combn.o choose.o
```

**Linux**

Under Linux, DLL files usually have a `.so` extension (for shared object). You should thus replace all occurrences of extension `.dll` by extension `.so`.

**Mac**

Under MacOS, DLL files usually have a `.dylib` extension (for dynamic library). You should thus replace all occurrences of extension `.dll` by extension `.dylib`. Also note that under MacOS, you must replace `g++ -shared` with `g++ -dynamic`.

In R, after changing to the correct directory, we can now execute the following instructions:

```
> combn(5, 3)
[1,]  1  1  1  1  1  1  2  2  2  3
[2,]  2  2  2  3  3  4  3  3  4  4
[3,]  3  4  5  4  5  4  5  5  5  5
> source("combn.R")
> combnRC(5, 3)
[1,]  1  1  1  1  1  1  2  2  2  3
[2,]  2  2  2  3  3  4  3  3  4  4
[3,]  3  4  5  4  5  4  5  5  5  5
> system.time(x <- combn(200, 3))
user  system elapsed
14.803  0.229  15.035
> system.time(x <- combnRC(200, 3))
user  system elapsed
0.158  0.023  0.181
```

There is an important speed-up thanks to this new R function using code written in C/C++.
Do it yourself

Code in R alone, and then in hybrid R-C/C++ (or R-Fortran), the functions \texttt{ar1simR()} and \texttt{ar1simRC()} - \texttt{ar1simC} (or \texttt{ar1simRF()} - \texttt{ar1simF}). These functions take three input arguments: \( n \in \mathbb{N}, \phi \in (-1, 1) \) and \( M \in \mathbb{N} \). They do the following computations.

For \( m = 1, \ldots, M \):

a) simulate random vector \( \epsilon = (\epsilon_1, \ldots, \epsilon_n)^T \) with distribution \( \mathcal{N}_n(0; I_n) \);

b) create vector \( x = (x_1, \ldots, x_n)^T \), with \( x_1 = \epsilon_1 \), and such that for all \( t = 2, \ldots, n \), we have \( x_t = \phi x_{t-1} + \epsilon_t \);

c) calculate the conditionnal least squares estimator \( \hat{\phi}_m \) of \( \phi \):

\[
\hat{\phi}_m = \frac{\sum_{t=2}^n x_{t-1}x_t}{\sum_{t=2}^n x_{t-1}^2}.
\]

The functions you create should output the value \( \bar{\hat{\phi}} = \frac{1}{M} \sum_{m=1}^M \hat{\phi}_m - \phi \), thus allowing a numerical evaluation of the bias of estimator \( \hat{\phi} \) of \( \phi \).

Compare the speed of execution of the pure R version with the version calling C/C++ (or Fortran) code. To this end, plot the values \( (M, \text{time}_M) \) for \( M = 1000, 2000, \ldots, 100\,000 \). Take \( n = 1000 \) and \( \phi = 0.75 \).

Note: The function \texttt{arima.sim()} performs parts a) and b) above, and function \texttt{arima()} performs part c). Do not use these two pre-existing functions for this exercise: they are very fast because they are coded in C, but are not limited to the previous computations.

Tip

To ease code development, a good editor is always useful. An editor should at least include indentation and syntactical colouring. You may wish to use the following free software:

- an R code editor such as RStudio, Tinn-R or Emacs;
- a source code editor for C/C++ and Fortran such as Emacs or Code::Blocks (available at http://www.codeblocks.org).
The package `rbenchmark` can be used to easily calculate the expected gain in computation time by using an R-C/C++ or R-Fortran function rather than a pure R function. For example, try to verify the results we got in the previous practical using the following code:

```r
n <- 1000
phi <- 0.75
M <- 2000
dyn.load("ar1sim.dll")
benchmark(Rcode=ar1simR(n,phi,M),
        Ccode=.C("ar1simC",as.integer(n),phi,
               as.integer(M),res=0.0)$res,
        replications=1000)
```

Fortran and R store matrices (tables) in the same way: the rows of a given column are stored sequentially in memory. In C/C++, the opposite holds; columns of a given line are stored sequentially. Be careful when sending a matrix from R to C/C++. For example, the element with index \([i,j]\) in an R matrix corresponds to the element with index \([(j-1) \times \text{number-of-rows} + (i-1)]\) in C/C++ (in C/C++, indices start at 0).

### 6.5.3 Calling external C/C++ or Fortran libraries

It is possible to use a function from an external library thanks to the R functions `.C()` (for C/C++ libraries) and `.Fortran()` (for Fortran libraries).

```
# Select file C:/windows/system32/user32.dll:
dyn.load(file.choose())
.C("LockWorkStation")
```

It is also possible to call an external library directly from your C/C++ or Fortran code. Here are some scientific libraries which we find interesting:
- the C API (Application Programming Interface) in R;
6.5 Interfacing R and C/C++ or Fortran

- the C++ library newmat;
- the Fortran libraries BLAS and LAPACK.

See also

Other libraries exist; some are free of charge, or even open-source, such as:

- in C/C++:
  - http://www.gnu.org/software/gsl/
  - http://www.math.uiowa.edu/~dstewart/meschach/
  - http://www.nrbook.com/a/bookcpdf.php

- in Fortran:
  - http://calgo.acm.org/
  - http://math-atlas.sourceforge.net/

others are not free:

- in C/C++:
  - http://www.nag.co.uk/numeric/CL/CLdescription.asp

- in Fortran:
  - http://www.nag.co.uk/numeric/RunderWindows.asp
  - http://www.nag.co.uk/numeric/fl/FLdescription.asp
  - http://www.nag.co.uk/numeric/fn/FNdescription.asp

6.5.3.1 The R API

The R API is a library created by the R developers. It can be used from a C/C++ program without even using R (it is then called Standalone R API). It can also be used in C/C++ code which will itself be called from R, as introduced in the previous section. This allows the use of existing routines without having to rewrite them. To use this library, you must include in your C/C++ source code the two header files R.h and Rmath.h, which are necessary to declare or define some mathematical functions and constants.
We present below C/C++ code available at `http://biostatisticien.eu/springeR/integ.cpp` which allows to compute the integral

\[
\int_{\epsilon_1}^{\infty} \Phi(t + \epsilon_2) dt,
\]

where \(\epsilon_1\) and \(\epsilon_2\) are realisations of two independent random variables (respectively normal and uniform) and where \(\Phi(\cdot)\) is the cumulative distribution function of the \(N(0,1)\) distribution. The only point of this example is to illustrate the use of the R API to simulate random variables, calculate a probability and perform numerical integration.

```c
#include <R.h>
#include <Rmath.h>

extern "C" {

typedef void integr_fn(double *x, int n, void *ex);
void f(double *t, int n, void *ex);
void test_integral(double *res) {

    // R API numerical integration function
    void Rdqags(integ_fn f, void *ex, double *a, double *b, double *epsabs,
                double *epsrel, double *result,
                double *abserr, int *neval,
                int *ier, int *limit, int *lenw,
                int *last, int *iwork, double *work);

    GetRNGstate(); // Read the R generator seed

double *a, *b, *epsabs, *epsrel, *result,
    *ex, *abserr, *work;

    ex = new double[1]; a = new double[1];
    b = new double[1]; epsabs = new double[1];
```

Interfacing R and C/C++ or Fortran

```c
epsrel = new double[1]; result = new double[1];
abserr = new double[1]; neval = new int[1];
ier = new int[1]; limit = new int[1];
lenw = new int[1]; last = new int[1];
limit[0] = 100;
lenw[0] = 4 * limit[0];
iwork = new int[limit[0]]; work = new double[lenw[0]];

a[0] = rnorm(0.0, 1.0); // eps1 from N(0,1)
b[0] = M_PI; // The constant \pi (3.141593...)
ex[0] = runif(0.0, 1.0); // eps2 from Unif(0,1)

// Calculate the integral
Rdqags(f, ex, a, b, epsabs, epsrel, result, abserr, neval, ier, limit, lenw, last, iwork, work);

// The result is stored in res[0]
res[0] = result[0];
PutRNGstate(); // Write the generator seed

// Free up some memory
delete[] ex, a, b, epsabs, epsrel, result, abserr, neval, ier, limit, lenw, last, iwork, work;

// Define the function to integrate
void f(double *t, int n, void *ex) {
    int i;
double eps2;
    eps2 = ((double*)ex)[0];
    for (i=0; i<n; i++) {
        t[i] = pnorm(t[i]+eps2, 0.0, 1.0, 1, 0);
    }
}
```

The instructions to compile this function in order to get a DLL file are:

```
g++ -c integ.cpp -o integ.o -I"C:\Program Files\R\R-2.15.1\include"
g++ -shared -o integ.dll integ.o -L"C:\Program Files\R\R-2.15.1\bin\i386" -lR
```
Warning

Note that we had to indicate the paths to the folders containing the files R.h, Rmath.h and R.dll. Modify these as needed depending on your system configuration. In MS-DOS, the symbol ` indicates an incomplete line.

Linux

```
g++ -c integ.cpp -o integ.o -I"/usr/lib/R/include" -fPIC
g++ -shared -o integ.so integ.o -I"/usr/lib/R/include" \ 
   -L"/usr/lib" -lR
```

Now, to perform the calculation in R, use the following instructions:

```
> dyn.load(paste("integ",.Platform$dynlib.ext,sep=""))
> # i.e. dyn.load("integ.dll") under Windows.
> .C("testintegral",val=0.0)$val
```

[1] 3.707762

Of course, the result of this computation varies, depending on the realisations of $\epsilon_1$ and $\epsilon_2$.

6.5.3.2 The `newmat` library

The `newmat` library is used to manipulate various types of matrices and to perform classical operations such as: multiplication, transposition, inversion, eigenvalue computation, decompositions, etc.

See also

The complete documentation for this library is available at: http://www.robertnz.net/nm11.htm

The code below, available at http://biostatisticien.eu/springeR/inv.cpp, is C/C++ code using this library to invert a matrix and can be called from R.

```
#define WANT_STREAM
#define WANT_MATH
#include "newmatap.h"
#include "newmatio.h"
#if define use_namespace
using namespace NEWMAT;
#endif
extern "C" {
  void invC(double *values, int *nrow) {
```
6.5 Interfacing R and C/C++ or Fortran

```c
int i, j;
Matrix M(nrow[0], nrow[0]);
M <<- values;
M <<- M[i()]; // Calcul de l'inverse de M
for (i=1; i<=nrow[0]; i++) {
    for (j=1; j<=nrow[0]; j++) {
        values[nrow[0]*(i-1)+j-1] = M(i, j);
    }
    M.Release();
    return;
}
```

Tip

Download file [http://www.robertnz.net/ftp/newmat11.zip](http://www.robertnz.net/ftp/newmat11.zip) and unzip it in C:/newmat. Then type the following instructions in an MSDOS window:

```bash
cd \
cd newmat
g++ -02 -c *.cpp
ar cr newmat.a *.o
ranlib newmat.a
cp newmat.a newmat.dll
```

After a few minutes, the libraries newmat.a and newmat.dll are created in folder C:\newmat.

You now need to create the library inv.dll (ou inv.so under Linux) using the following instructions:

```bash
cd folder containing file inv.cpp
g++ -IC:\newmat -o inv.o -c inv.cpp
R CMD SHLIB inv.cpp -IC:\newmat C:/newmat/newmat.a
```

You can then use the C/C++ above from R as follows. First save the following code in a file called inv.R:

```R
```
> inv <- function(M) {
+   n <- nrow(M)
+   return(matrix(.C("invC", Minv=as.vector(M), n)$Minv, nrow=n, ncol=n))
+ }

Then execute the instructions:

> dyn.load(paste("inv",.Platform$dynlib.ext,sep=""))
> A <- matrix(rnorm(9),nrow=3)
> solve(A) # The R function solve() inverts a matrix.
[,1]    [,2]    [,3]
[1,]  0.0993572 0.04676191 1.155500
[2,] -0.47035376 1.10728717 -2.979609
[3,]  0.03415044 -1.07683806 1.456918
> inv(A)
[,1]    [,2]    [,3]
[1,]  0.0993572 0.04676191 1.155500
[2,] -0.47035376 1.10728717 -2.979609
[3,]  0.03415044 -1.07683806 1.456918

The two functions solve() and inv() thus give the same result for matrix inversion. As you can see, the speed-up for this operation is substantial.

> benchmark(Rcode=solve(A),Ccode=inv(A),replications=10000)

<table>

</table>

6.5.3.3 The BLAS and LAPACK packages

The BLAS (Basic Linear Algebra Subprograms) and LAPACK (Linear Algebra PACK-age) packages are Fortran packages which perform many matrix operations. We shall see how to use them on a simple example.

First download the archiver software 7-zip available at http://www.7-zip.org/download.html. Use this software (twice) to unzip (in two steps) the file http://www.netlib.org/lapack/lapack.tgz. All files and subfolders (BLAS, CMAKE, etc.) should be placed directly in a folder called C:\lapack. For example, this folder will contain at its root a file called make.inc.example, which you must rename to make.inc after changing the line SHELL = /bin/sh to SHELL = sh. Then type the following instructions in an MS-DOS window:

```bash
cd C:\lapack
make lapacklib blaslib
```

After several minutes, the static packages librefblas.a and liblapack.a are created.
The documentation for these packages can be read at http://www.netlib.org/lapack/lug. It is also useful to read the source code of all BLAS and LAPACK routines you wish to use, as they contain a detailed description of the arguments the routines take.

Here is the Fortran code, also available at http://biostatisticien.eu/springerR/inv.f90, for a subroutine which computes the inverse of a matrix. It uses the subroutines external DGETRF and DGETRI from the Lapack package.

```
! Returns the inverse of a matrix calculated by finding
! the LU decomposition. Depends on LAPACK.
subroutine invF(A, Ainv, m)
  double precision, dimension(m,m), intent(in) :: A
  double precision, dimension(size(A,1),size(A,2)), &
     intent(inout) :: Ainv
  ! work array for LAPACK
  double precision, dimension(size(A,1)) :: work
  integer, dimension(size(A,1)) :: ipiv ! pivot indices
  integer :: n, info, m
  ! External procedures defined in LAPACK
  external DGETRF
  external DGETRI

  ! Store A in Ainv to prevent it from
  ! being overwritten by LAPACK
  Ainv = A
  n = size(A,1)

  ! DGETRF computes an LU factorization of
  ! a general M-by-N matrix A using partial
  ! pivoting with row interchanges.
  call DGETRF(n, n, Ainv, n, ipiv, info)

  if (info /= 0) then
    stop 'Matrix is numerically singular!'
  end if

  ! DGETRI computes the inverse of a matrix using
  ! the LU factorization computed by DGETRF.
  call DGETRI(n, Ainv, n, ipiv, work, n, info)
```
To compile this code, execute the following instructions from an MS-DOS window:

```bash
cd %HOMEPATH%/Desktop # To be changed to suit your needs.
gfortran -c inv.f90 -o inv.o -I"C:/lapack"
gfortran -shared -o inv.dll inv.o -I"C:/lapack" -L"C:/lapack/liblapack.a C:/lapack/librefblas.a
```

Under Linux, use the following instructions:

```bash
gfortran -c inv.f90 -o inv.o -fPIC
gfortran -shared -o inv.so inv.o /usr/lib64/liblapack.so.3
```

After creating the file inv.dll (or inv.so under Linux) with the previous instructions, you can start R and type the following instructions:

```R
> dyn.load(paste("inv",.Platform$dynlib.ext,sep=""))
> A <- matrix(rnorm(4),nrow=2)
> B <- matrix(0,nrow=2,ncol=2)
> .Fortran("invF",A,res=B,2L)$res
   [,1]      [,2]
[1,] -1.181274  1.982253
[2,] -0.168151 -0.722435
> solve(A)
   [,1]      [,2]
[1,] -1.181274  1.982253
[2,] -0.168151 -0.722435
```

### 6.5.3.4 Mixing C/C++ and Fortran packages

It is possible to call C/C++ functions from Fortran code, thanks to the instruction `F77_SUB(name)`. We illustrate this point in the next example, which generates two independent observations: one from a \(N(0, 1)\) distribution and the other from the uniform distribution. The Fortran code below uses the C functions `GetRNGstate`, `PutRNGstate`, `rnorm` and `runif` from the R API, which we have already used in section 6.5.3.1. Save it in a file called `random.f`.

```fortran
1    SUBROUTINE random(x,y)  
2        real*8 normrnd, unifrnd, x, y  
3        CALL rndstart()  
4        x = normrnd()
```
6.5 Interfacing R and C/C++ or Fortran

Then create the file `random.c` containing:

```c
#include <R.h>
#include <Rmath.h>

void F77_SUB(rndstart)(void) { GetRNGstate();

void F77_SUB(rndend)(void) { PutRNGstate();

double F77_SUB(normrnd)(void) { return rnorm(0,1);;

double F77_SUB(unifrnd)(void) { return runif(0,1);
```

To create your DLL file, compile using the instructions:

```
gfortran -c random.f -o randomf.o
gcc -c random.c -o randomc.o -I"C:\Program Files\R\R-2.15.1\include"
gfortran -shared randomf.o randomc.o -o random.dll
-L"C:\Program Files\R\R-2.15.1\bin\i386" -lR
```

Under Linux, use

```
gfortran -c random.f -o randomf.o -fPIC
gcc -c random.c -o randomc.o -I"/usr/lib/R/include" -fPIC
gfortran -shared randomf.o randomc.o -o random.so
```

You can now call your code from R using the instructions:

```r
> dyn.load(paste("random",.Platform$dynlib.ext,sep=""))
> .Fortran("random", as.double(1), as.double(1))
[[1]]
[1] 1.542474
[[2]]
[1] 0.59143
```

It is also possible to call Fortran functions from C/C++ code, using the following instructions:

- `F77_NAME(name)` to declare a Fortran routine in C
- `F77_CALL(name)` to call a Fortran routine from C
- `F77_COMDECL(name)` to declare a COMMON FORTRAN block in C
- `F77_COM(name)` to access a COMMON FORTRAN block from C

Here is a small example (with Fortran77 for a change). Save the code below in a file called `combnCF.cpp`:

```c
5    y = unifrnd()
6    CALL rndend()
7    RETURN
8    END
```

```c
1 # include < R . h >
2 # include < Rmath . h >
3 void F77_SUB( rndstart )( void ) { GetRNGstate();
4 void F77_SUB( rndend )( void ) { PutRNGstate();
5 double F77_SUB( normrnd )( void ) { return rnorm(0,1);;
6 double F77_SUB( unifrnd )( void ) { return runif(0,1);;
```
Programming in R

```c
#include <R.h>
#include <Rmath.h>
extern "C"
{
  void combnCF(int *combmat, int *n, int *m) {
    // Caution! No upper case in the name of the subroutine.
    void F77_NAME(combnf)(int *combmat, int *n, int *m);
    F77_CALL(combnf)(combmat, n, m);
  }
}
```

Then type the following instructions in an MS-DOS command window to create the package which will be called from R:

```
g++ -c combnCF.cpp -o combnCF.o -I"C:\Program Files\R\R-2.15.1\include"
gfortran -c combn.f90 -o combn.o
g++ -shared -o combnCF.dll combnCF.o combn.o
    -L"C:\Program Files\R\R-2.15.1\bin\i386" -lR
```

Under Linux:

```
g++ -c combnCF.cpp -o combnCF.o -I"/usr/lib/R/include" -fPIC
gfortran -c combn.f90 -o combn.o -fPIC
g++ -shared -o combnCF.so combnCF.o combn.o
    -I"/usr/lib/R/include" -L"/usr/lib" -lR
```

Now modify the code of function `combnRC()` given page 235:

- change the name of this function to `combnRCF()`;
- replace "combn" and "combnC" with "combnCF".

Save this new code in a file called `combnCF.R`. Then type the following instructions in the R console:

```
> source("combnCF.R")
> combnRCF(5,3)
[1,] 1 1 1 1 1 1 1 1 2 2 2 3 3 3 4 4 4 4
[2,] 2 2 2 3 3 4 3 3 4 4 4 5 5 5 5 5 5 5

6.5.4 Calling R code from a C/C++ program called by R

We have seen how to call a C/C++ (or Fortran) routine from R. It is also possible to use a type of pointer called SEXP (for Simple Expression) and the function
Interfacing R and C/C++ or Fortran

In this subsection, we only give a simple example. The reader can use this as inspiration for more complex examples.

See also

We refer the reader to the website http://cran.r-project.org/doc/manuals/R-extern.html#Handling-R-objects-in-C.

In the following example, we shall see how to call function pmvt() of package mvtnorm from C/C++ code, itself called from R. The function pmvt() computes the probability that a random vector following a multivariate Student distribution belongs to a specified hyperrectangle in \( \mathbb{R}^n \).

Unlike the examples in the previous sections, which used the function .C(), we shall need the function .Call(). Furthermore, our C/C++ code will have to be a function (which we call pmvtC in the following) which returns a structure of type SEXP and which also takes arguments of type SEXP. The code below, available from http://biostatisticien.eu/springeR/pmvt.cpp, will be transformed into a DLL file then called by the function .Call().

To compile this file, use the following instructions:

g++ -c pmvt.cpp -o pmvt.o -I"C:\Program Files\R\R-2.15.1\include"
g++ -shared -o pmvt.dll pmvt.o -L"C:\Program Files\R\R-2.15.1\bin\i386" -lR
Under Linux, use the instructions:

```
g++ -m64 -I/usr/include/R -I/usr/local/include -fpic \  -c pmvt.cpp -o pmvt.o  
R CMD SHLIB pmvt.cpp
```

# or:
```
g++ -m64 -shared -L/usr/local/lib64 -o pmvt.so pmvt.o \  -L/usr/lib64/R/lib -lR
```

You can now call this function from R. First download the file http://biostatisticien.eu/springerR/pmvt.R which contains the following code:

```r
> pmvtRCR <- function(upper,corr,df) {
+ res <- 0.0
+ Rpmvt <- function(upper,corr,df) {
+ d <- length(upper)
+ pmvt(lower=rep(-Inf,d),upper=upper,delta=rep(0,d),
+ corr=matrix(corr,ncol=d),df=df)
+ dyn.load(paste("pmvt",.Platform$dynlib.ext,sep=""))
+ res <- .Call("pmvtCR",as.double(upper), as.double(corr),
+ as.double(df),Rpmvt,new.env(),as.double(res))
+ dyn.unload(paste("pmvt",.Platform$dynlib.ext,sep=""))
+ return(res)
+ }
> require(mvtnorm)
> corr <- diag(3)
> set.seed(1)
> source("pmvt.R")
> pmvtRCR(c(2,3,2),corr,c(1,1,1))
[1] 0.706062
> pmvt(lower=rep(-Inf,3),upper=c(2,3,2),corr=corr,df=c(1,1,1))
[1] 0.706062
```

**Tip**

If an SEXP object contains a vector (for example SEXP x) or a matrix (for example SEXP M), you can use the instructions `R_len_t n = length(x)` and `R_len_t p = nrows(M)` to create integers containing the length n of vector x or the number p of rows of matrix M. The file `Rinternals.h` contains the list of many similar useful functions.
6.5.5 Calling R code from Fortran

We recommend the Open-Source software RFortran available at http://www.rfortran.org.

6.5.6 Some useful functions

Here are a few functions which you may find useful. The following functions are used in an MS-DOS terminal window (or in Cygwin, see page 256):

- **nm**: List of symbols of object files (e.g. `nm random.dll`).
- **objdump**: Information about object files (e.g. `objdump -x random.dll`).
- **ldd**: List dynamic dependencies if necessary (e.g. `ldd random.dll`).

The following functions are used in R:

- **getLoadDLLs()**: List all DLLs loaded in the current session (e.g. `getLoadDLLs()`).
- **is.loaded()**: Checks whether a library is loaded (e.g. `is.loaded(random.dll)`).

SECTION 6.6

† Debugging functions

In this section, we present various options which can be useful to debug a function and find an error. The error could be either in the R code, or in C/C++ or Fortran code called from your R function.

### 6.6.1 Debugging functions in pure R

We present some debugging functions, useful when writing R code.

The function **browser()**

A useful debugging function in R is the function `browser()`. If you insert the instruction `browser()` in the source of your function, the program will stop at the place where it was inserted.
Here is an example showing how to use \texttt{browser()} in a function called \texttt{lsq()} which calculates the least squares estimator of unknown arguments in a simple linear model (see Chapter 12 for further details).

\begin{verbatim}
lsq <- function(X, Y, intercept=T)
  X <- as.matrix(X)
  Y <- as.matrix(Y)
  plot(X, Y)
  nbunits <- nrow(X)
  browser()
  if (intercept==T) X <- cbind(rep(1, nbunits), X)
  betahat <- solve(t(X)%*%X)%*%t(X)%*%Y
  curve(betahat[1]+betahat[2]*x, add=TRUE)
return(betahat)
\end{verbatim}

Source the file containing the previous code (for example with the instruction \texttt{source(file.choose())}), then type:

\texttt{lsq(X=cars[,2], Y=cars[,1])}

As you can see, the program stops and you can examine the contents of all local variables defined before \texttt{browser()}. For example, type \texttt{nbunits}.

\textbf{Note}

By typing the letter \texttt{n} (for \texttt{next}), you can inspect the code and the contents of variables sequentially. To leave the inspection mode, type \texttt{Q}.

Here is an overview of a debugging session:

\begin{verbatim}
lsq(X=cars[,2], Y=cars[,1])
Called from: mc(X = cars[, 2], Y = cars[, 1])
Browse[1]> nbunits
[1] 50
Browse[1]> betahat
Error: Object "betahat" not found
Browse[1]> n
debug: if (intercept == T) X <- cbind(rep(1, nbunits), X)
Browse[1]> n
debug: betahat <- solve(t(X) %*% X) %*% t(X) %*% Y
Browse[1]> n
Browse[1]> betahat
[,1]
[1,]  8.2839056
[2,]  0.1655676
Browse[1]> Q
> \end{verbatim}
Note

If you enter the letter c (for continue), the code is executed until the end, unless a browser() command is met again.

The function debug()

Another interesting function is debug() which is equivalent to putting the instruction browser() at the top of a function. Thus debug(var) marks the functions var as debuggable. Any subsequent call of this function will launch the online debugger.

```
debug(var)
var(1:3)
```

To get rid of this mark, use the function undebug().

```
undebug(var)
```

6.6.2 Error in R code

First change line 6 of file comb.R, replacing the affectation arrow <- by the symbol <. We now have an error: an ommited symbol (the symbol -):

```
combmat<matrix(out$res,nrow=m,byrow=F)
```

Save the file, source it and type the following instruction:

```
> combnRC(5,3)
[1,]    0    0    0    0    0    0    0    0    0    0
[2,]    0    0    0    0    0    0    0    0    0    0
[3,]    0    0    0    0    0    0    0    0    0    0
```

As you can see, there is an error in the result, and the error that we introduced deliberately in the code could be difficult to detect if it were an accidental omission. Here is how we could try to detect where the error comes from. First install and load the package debug. Then use the function mtrace() of this package, as follows:

```
mtrace(combnRC)
combnRC(5,3)
```

You should then see a debugging window with the source code of function combnRC(). Pressing the RETURN key repeatedly will evaluate your source code line by line until the next display (which occurs upon evaluation of the line we modified):
This hints that there is an issue at this point. We can then correct the error, for example with the instruction `fix(combnRC)`.

Note that the function `mtrace()` did not allow us to delve into the details of the following call:

```
.C("combnC",res=as.integer(compmat),as.integer(n),
    as.integer(m))
```

### 6.6.3 Error in the C/C++ or Fortran code

We shall now see how to perform the same kind of debugging for parts of the code written in C/C++ or Fortran. It mostly boils down to using the compilation option `-g` to add information on the source code in the DLL file, and then to using a specialized debugging tool.

**Warning**

You will need a debugging tool. We recommend the free software GDB. Download version 7.4 (32 bits) from `http://biostatisticien.eu/springeR/32/gdb.exe` and put it in the folder `C:\Rtools\bin`. This software uses the command line and is rather austere. You may find useful to add a Graphical User Interface (GUI), such as the Data Display Debugger (DDD) or Emacs. Under Windows, another interesting avenue is the software Insight, included in the set of tools MinGW, available from `http://sourceforge.net/projects/mingw/files/OldFiles/insight.exe/download`. However, this software seems to be becoming obsolescent. If you try to use it, remember to change the system environment variable `Path` to add the path to Insight (probably `C:\insight\bin`), as explained page 229.

Under Microsoft Windows, you will have to install the version of Emacs available at `http://vgoulet.act.ulaval.ca/en/emacs/windows`. It is a bit more complicated to use DDD under Windows. You need to launch the Cygwin setup (available at `http://cygwin.com/setup.exe`), choose the installation directory `C:\Rtools\bin` and select the software Devel: ddd and Math: gnuplot (and accept the required dependencies). Also note that if the list of download sites is empty, you can try the URL `http://cygwin.mirrorcatalogs.com`. To use DDD, you also need an implementation of the Linux X window system for Microsoft Windows. The

### 6.6.4 Debugging with GDB

Start an MS-DOS command window from the Windows Start menu (type cmd) in which you type:

```
cd path to folder containing inv.cpp
   g++ -IC:\newmat -o inv.o -c inv.cpp -g
   g++ -shared -o inv.dll inv.o -IC:\newmat C:/newmat/newmat.a
```

This will create the file inv.dll with debugging information (see page 245 for the creation of the library newmat).

**Tip**

In order to also debug the functions from library newmat, you need to first create this library in a way that includes debugging information:

```
cd 
   cd newmat
   g++ -c *.cpp -Wno-deprecated -g
   ar cr newmatdebug.a *.o
   ranlib newmatdebug.a
   cp newmatdebug.a newmatdebug.dll
```

Then type:

```
gdb Rgui
   (gdb) run
```

This should start R, where you type:

```
> setwd("path to file inv.dll")
> dyn.load("inv.dll")
```

Then go to menu Misc/Break to debugger, which will allow you to return to GDB (black window), where you can type:

```
   (gdb) info share
   (gdb) break inv.cpp:1
   (gdb) signal 0
```
The first instruction (\texttt{info share}) shows that the library \texttt{inv.dll} has been loaded; the second instruction (\texttt{break inv.cpp:1}) allows you to add a break point on the first (executable) line of the file \texttt{inv.cpp}; the last instruction (\texttt{signal 0}) exits GDB and returns to R. In R, type:

\begin{verbatim}
> A <- matrix(rnorm(4),nrow=2)
> source("inv.R")  # File created page 245.
> inv(A)
\end{verbatim}

When the processor encounters the break point, the code execution is suspended. You can now type the following instructions in GDB. The first instruction (\texttt{list}) display the next lines to execute; the second instruction (\texttt{next}) moves to the next line; the third instruction (\texttt{print nrow[0]}) displays the value of \texttt{nrow[0]}, and the last instruction continues the code execution until the end or the next break point.

\begin{verbatim}
(gdb) list
(gdb) next
(gdb) print nrow[0]
(gdb) continue
\end{verbatim}

You are back in R and you see the output of the call \texttt{inv(A)}. You can type the following instructions to verify that the result is the same as with function \texttt{solve()}, and to exit R.

\begin{verbatim}
> solve(A)
> q()
\end{verbatim}

Under Linux, type in a terminal window the command:

\begin{verbatim}
R -d gdb
\end{verbatim}

instead of \texttt{gdb Rgui}.

Alternatively, you could use the following instructions:

\begin{verbatim}
export R_HOME=/usr/lib64/R
gdb /usr/lib64/R/bin/exec/R
\end{verbatim}

To return to R from GDB, use the key combination \texttt{CTRL+C}. Note that to go from GDB to R, after typing \texttt{signal 0} (or equivalently \texttt{c}), you need to press RETURN.

\textbf{Tip}

Note that GDB can be called with options. For example:

\begin{verbatim}
--directory=DIR  Search for source files in DIR.
--pid=PID  Attach to running process PID.
\end{verbatim}
See also

Tip

You can install/compile a package (hereafter called PKG) with debugging information (equivalent to using the flag `-g` mentioned above). First create a file called `Makevars.win` (`Makevars` under Linux) in a subfolder called `.R` in your `%HOME%` directory. This file should include the following lines:

```
## for C++ code
CXXFLAGS=-g
```

For this purpose, you can for example type: `WINDOWS+R`, *cmd*, `ENTER`, `cd %HOME%`, `ENTER`, `mkdir .R`, `ENTER`, `cd .R`, `ENTER`, `echo CXXFLAGS=-g > Makevars.win`, `ENTER`. Next, build the package PKG and install it (from the sources using the command `R CMD INSTALL --build --debug PKG`), then use one of the debugging methods presented above. Note that the file `NAMESPACE` of your package PKG must include the line `useDynLib("PKG")` so that the DLL (or `.so`) file is automatically loaded when you execute in R the instruction `require(PKG)`. If this procedure fails, you can always use the function `dyn.load()` to load the package “by hand” from where it is installed.

Tip

It is also possible to display the contents of an object of type `SEXP` (call this object `s`). To do this, you can include in your C/C++ code the instruction `PrintValue(s);`. This way, when the instruction is encountered during code execution, the contents of the object `s` will be displayed in the R console. Another solution is to use the instruction `p Rf_PrintValue(s)` from the GDB console. Note that in this case, the display of object `s` in the R console may be delayed until R takes over from GDB.

6.6.4.1 Debugging with Emacs

We have seen how to debug code with GDB. We shall now show how to perform the same kind of operations with the combination of Emacs (and its excellent module ESS, *Emacs Speaks Statistics*) and GDB. Note that you need to have installed GDB as explained page 6.6.3. Note also that you need to create, from an MS-Dos window,
the file `combn.dll` with debugging information (flag `-g`) thanks to the following instructions:

```bash
  g++ -g -c combn.cpp -o combn.o
  g++ -shared -o combn.dll combn.o
```

**Under Emacs**, the notation `M-x` means you must press simultaneously the keys ALT and X, whereas `C-x` means you must press simultaneously the keys CTRL and X, and `[RET]` designates the carriage return (key RETURN).

First open Emacs (see page 256 for how to install this software) then execute the following commands. For example, the first line is executed by pressing simultaneously on ALT and X, then R (which will display `M-x R` at the bottom of Emacs), then RETURN (which will display ESS [S(R): R (newest)] starting data directory? `/`), then RETURN again (which will start R in Emacs).

```
  M-x R [RET] [RET]
  M-x gdb [RET] gdb -i=mi --annotate=3 [RET]
```

Your Emacs window should then be split in two, with R on top and GDB at the bottom. If that is not the case, go to the menu File/Split Window or File/New Window Below (C-x 2), then to the menu Buffer to select `*R*`.

**Warning**

The system environment variable Path must include the entry `C:\Rtools\bin` first, so that the version of GDB used is 7.4.

You then need the process ID of R. Under Windows, use the key combination CTRL+ALT+Del to start the task manager. Then select the Processes tab. In the menu View/Select Columns..., tick the box PID (Process Identifier), which will add a column PID to the task manager. Then find the (PID) corresponding to the name `Rterm.exe *32` (for example 5404).

**Linux**

```
  M-! Shell command: pgrep R [RET]
```

Then type in Emacs the following instructions:

```
  (gdb) attach 5404 [RET]
  (gdb) signal 0 [RET]
```

Click on the panel (or Buffer in Emacs) called `*R*`, and execute the following instructions:
6.6 Debugging functions

> setwd("chemin vers le fichier combn.R")
> source("combn.R")
> dyn.load(paste("combn", .Platform$dynlib.ext, sep=""))

Click on the bottom sub-window (*Buffer* "gud").

C-c C-c
(gdb) b combn.cpp:1 [RET]
(gdb) c [RET]

Click on the top sub-window (*Buffer* "R")

> combnRC(5, 3)

C-g
M-x gdb-many-windows

Put the *Emacs* window in full screen. Your *Emacs* window should now be divided in six panels, as shown in figure 6.2. If needed, click on the relevant entries of the *Buffer* menu.

![Emacs and GDB](image)

**Fig. 6.2:** *Emacs* and *GDB*.

Click on the bottom right panel called "breakpoints of". Select the menu *Buffers*/"R" *

Now click on the window combn.cpp. You will see new icons in the top part of *Emacs*. For example, you can click on the symbol for Next Line (right of GO) to execute your C/C++ line by line.
### Do it yourself

- Change line 32 of file `integ.cpp` into `limit[0] = -1;`. Recompile this code and call it from R as seen above: `.C("testintegral", val=0.0)$val`. Your R session should crash. Suppose you do not remember making the above change. Use the techniques you just learnt to find the error.

- Debug the file `pmvt.cpp` seen in Section 6.5.4. Type the instruction `p Rf_PrintValue(Rpmvt)` from the GDB console to display (in the R console) the contents of object `Rpmvt`.

### 6.6.4.2 Debugging with DDD

You first need to launch Xming (or an equivalent tool); its icon should appear in the task bar. Then launch a Cygwin terminal window, and type the following instructions:

```
$ export DISPLAY=localhost:0.0
$ cd path to directory containing the source and DLL files
$ ddd Rgui
```

You may need to wait a while before DDD starts.

Under Linux, replace the last instruction with the command `R --debug ddd`.

Next, type the following instructions in GDB (lower panel):

```
(gdb) dir $cwd
(gdb) run
```

The first instruction tells GDB to search for source files in the current directory (which would be given by the command `pwd`), thus avoiding issues due to path management in Windows. The second instruction starts R (you could also tick the box: Program/Run in Execution Window, and click on Program/Run, then on Run); type in R:

```
> dyn.load("inv.dll")
```

Note that the file `inv.dll` was created with debugging information, as mentioned page 257. Now go to menu Misc/Break to debugger to return to DDD. Go to menu File/Open source... and open file `inv.cpp`. Also tick the entry Data Window in menu View (and possibly entry Display Local Variables in menu Data, if you
are patient!). You can then put one or several breaking points in the code to debug (by double-clicking at the beginning of the line or by right-clicking), for example at the instruction `M << values;`. This has the effect of displaying a stop symbol. Then type `continue` (or just `c`) in the lower part (gdb). This returns to R, where you type:

```r
> A <- matrix(rnorm(4), nrow=2)
> source("inv.R") # File created page 245.
> inv(A)
```

When the (first) breaking point is encountered by the processor, code execution is suspended. You can now use the graphical tool DDD to debug your code.

Note that it is possible to display several values of an array. For example, you can type in the lower window (gdb) the following instruction:

```r
graph display values[0] @ 4
```

to display the (first) 4 values of array `values`.

---

**6.6.4.3 Debugging with Insight**

Insight seems to have difficulties working on some Windows versions. Nonetheless, we present this software for those who have a compatible version of Windows,
or in case a new version of Insight is shipped after the publication of this book.

Recompile your file using flag -g (and possibly -fPIC) which tells the C++ compiler to add information on the source code directly in the compiled file.

```
g++ -c combn.cpp -o combn.o -g
g++ -shared -o combn.dll combn.o
```

Then, from the MS-DOS window, execute insight Rgui.exe then click on Run.

Next type the following commands in the R console which opens:

```
> source("combn.R")
> dyn.load(paste("combn", .Platform$dynlib.ext, sep=""))
```

Go to the R menu called Misc, then Break to debugger. You are now in the Insight window.

In Insight, select menu View - Console [CTRL+N]. This opens the command window of debugger GDB. We can now add a breaking point to function `combnC` by typing:

```
break combnC
```

Then type:

```
continue
```

which returns to R. As soon as the function `combnC` is called, we will return to the debugger.

Now type in R:
Use instruction `n` (for `next`) to skip to the next instruction of our R code, until reaching the call to the function written in C++.

The breaking point we added is detected and we are back in Insight.

Next click on icon ![execute](image) to execute line by line the C++ code and check the value of the various variables.
The window **Local Variables** (shown by menu **View -> Local Variable [CTRL+L]**) displays all local variables and their contents during code execution.

Note that to see the contents of an **R** matrix or vector, you simply need to go to the **GDB** console and type for example:

```
x/30dw combmat
```

You can also display graphically this table of values and select it by clicking on **plot**.

You can now type the following instructions in the **GDB** console to add a breaking point at line 32 of your **C++** code, then re-execute the code. When the breaking point
is encountered, the code stops again and we can ask to display again the contents of array \( x \):

```bash
break 32
continue
x/30dw combmat
```

### 6.6.4.4 Detecting memory leaks

The messages *Segmentation fault* (or *segfault*), *invalid next size*, `std::bad_alloc` (which you will certainly encounter under Linux!), incoherent results, or, more radically, a complete crash of \( R \), are often indications that there is a memory issue (access to a non-reserved or non-initialized address, using freed memory, etc.) These memory leaks often occur when you have forgotten to use the instruction `delete[] ptr;` to delete from memory a pointer `ptr` introduced in a C/C++ function. This problem can sometimes be noticed in the task manager when you run a large simulation in \( R \) and realize that the \( R \) process is using more and more memory even though it should not.

**Linux**

Under Linux, the display of memory usage by different processes is given by the command (entered in a terminal window) `watch -d free` for global usage or by `top -p PID` for a specific process (use `ps au` to find the PID of the desired process). You can also use the graphical tool `ksysguard`.

Another common mistake is to try to manipulate the \( n \)th entry in an array of size less than \( n \) (accessing undefined memory). It can then be difficult to detect the origin of the problem. The software Dr Memory (http://code.google.com/p/drmemory), and possibly the software `electric-fence-win32` (http://code.google.com/p/electric-fence-win32) and duma (http://duma.sourceforge.net), can be precious tools in such situations.
Under Linux, you can use the software Valgrind or Electric Fence.

We now show on an example how to use Dr. Memory which you should install in the directory C:\drmemory (choose the entry Add Dr. Memory to the system PATH for all users upon installation).

The following piece of code includes several errors, which can be hard to find for a beginner. You can download it from http://biostatisticien.eu/springeR/memory.cpp.

```c
extern "C" {
void testmemory(int *M, double *a) {
    double *ptr1, *ptr2;
    int i;
    ptr1 = new double[10000];
    ptr2 = new double[M[0]];
    ptr1[0] = 1.0;
    for (i=1;i<10000;i++) {
        ptr1[i] = (double)i;
        ptr2[i] = ptr1[i-1] * (double)i;
    }
    delete [] ptr2;
    for (i=0;i<10;i++) a[i] = ptr2[i];
    return;
}
}
```

First create the associated DLL file, using the following instructions in an Ms-Dos window:

```sh
cd directory containing file memory.cpp
g++ -o memory.o -c memory.cpp -g
g++ -shared -o memory.dll memory.o
```

On Linux, use the instructions:

```sh
g++ -o memory.o -c memory.cpp -g -fPIC
g++ -shared -o memory.so memory.o
```

Next, type drmemory.exe -- Rgui in your command window (be patient), then type the following instructions in the R console:
Now look for the instances of `testmemory` in the file which opened up. This will indicate the lines which may contain errors. For example, this shows that there is an error at line 13. In fact, we realize that the array `a` is of length 1 (and initially contains only the value 3.0), whereas we are trying to write values in entries 0 to 9. Furthermore, the pointer `ptr2` was deleted on the preceding line.

You can also try the following `R` instruction, and note in the task manager that the amount of RAM used by `R` increases greatly. This is because we forgot the instruction `delete[] ptr1;` in the C/C++ code above.

```r
> for (i in 1:10000) .C("testmemory",10000L,as.double(1:10))
```

The equivalent of Dr Memory under Linux is called Valgrind. To detect where the leak comes from, you can use the instruction:

```bash
R -d 'valgrind --leak-check=full'
```

In the output of `valgrind`, you then need to look for the errors and for the corresponding line numbers in the source code of `memory.cpp`. The following instructions give other error types displayed by R and detected by Valgrind:

```r
> # Works only once!
> # Afterwards, R crashes with: "caught segfault":
> .C("testmemory",10000L,c(3.0,5.0))
> # R closes: "invalid next size":
> .C("testmemory",10000,c(3.0,5.0))
> # R closes: "std::bad_alloc":
> .C("testmemory",10^12,c(3.0,5.0))
> # Works when ptr2 is no longer defined:
> .C("testmemory",10000L,as.double(1:10))
```
Parallel computing and computation on graphical cards

6.7.1 Parallel computing

You can speed up your calculations by having them run on several processors at the same time; these processors can even be on different computers. There are several specialized packages for this; they are listed in the CRAN Task View: High-Performance and Parallel Computing with R, available at http://cran.r-project.org/web/views/HighPerformanceComputing.html.

The easiest to use is package snow with communication protocol SOCK, which we briefly describe below through an example.

Tip

The MPI protocol (Message Passing Interface), used by package Rmpi, is more flexible than the SOCK protocol, but it requires the installation of other software (such as OpenMPI or mpich2).

See also

The following R code performs numerical evaluation (by Monte Carlo simulation) of the empirical level of the Shapiro-Wilks normality test for a nominal level of 5%:

```r
> myfunc <- function(M=1000) {
+ decision <- 0
+ for (i in 1:M) {
+ x <- rnorm(100)
+ if (shapiro.test(x)$p < 0.05) decision <- decision + 1
+ }
+ return(decision)
+ }

Here is the computation time needed for this code with $M = 60,000$ Monte Carlo iterations:

```
We now show how this code can be parallelized using the package snow, and the corresponding gain in computation time. We used 6 processors. We also installed the package rsprng which handles the simulation of random numbers on the various processors of the cluster.

Tip

To know the number of processors on your computer, type the instruction devmgmt.msc in the menu Start/Run. Then count the number of lines in the Processors entry. Under Linux, type top in a terminal window, then 1. This shows the number of processors.

```r
> require(snow)
> system.time({
  + nbclus <- 6
  + M <- 60000
  + cl <- makeCluster(nbclus, type = "SOCK")
  + clusterSetupSPRNG(cl)
  + out <- clusterCall(cl, myfunc, round(M/nbclus))
  + stopCluster(cl)
  + decision <- 0
  + for (clus in 1:nbclus) {
  +   decision <- decision + out[[clus]]
  + }
  + print(decision/(round(M/nbclus)*nbclus))
  + })
[1] 0.0501
user system elapsed
0.019 0.033 5.522
```

6.7.2 Computation on graphical cards

The processor, or CPU (Central Processing Unit), is the computer component which handles execution of software. However, it is now also possible to perform computations on a GPU (Graphical Processing Unit), or graphical card. Graphical cards allowing such operations are marketed by Nvidia, and they can include hundreds of processors working in parallel. The speed-up in computation time can be substantial. To use this technology, however, you must know the programming language CUDA, developed by Nvidia. A few R developers have delved into this language and have grouped a few functions in the package gputools, which is only available on Linux for now.
Here is a short example of use of this package. We used an NVIDIA GeForce GTX 480 graphical card.

```r
> require(gputools)
> A <- matrix(runif(40000),nrow=200,ncol=200)
> B <- matrix(runif(40000),nrow=200,ncol=200)
> system.time(cor(A, B, method="kendall")) # Computation CPU.
  user  system elapsed
     29.804     0.002    29.810
> system.time(gpuCor(A, B, method="kendall")) # Computation on GPU.
  user  system elapsed
     0.836     0.052    0.891
```

To find out more on this topic, go to http://cran.r-project.org/web/packages/gputools/gputools.pdf and http://developer.nvidia.com/object/cuda_training.html.
Memorandum

function(<par1>,<par2>,...,<parN>) <body>: declare a function object
"["(): define a block of instructions and return the last evaluated instruction
class(): "class<-()": extract, affect the class of an object
missing(): test whether an effective argument is defined
attributes(): "attributes<-()": extract, affect all attributes as a list
attr(), "attr<-()": extract, affect a single attribute
expression(): create an expression object
parse(): convert text to an expression
eval(): evaluate an expression
"~()": create a formula object
new.env(): create an environment
local(): execute code locally in an environment

Exercises

6.1- For each of the following command lines, indicate the class of the returned R object. What is displayed upon execution of each of these command lines?

- function(name) {name}
- (function(name) {name})("Ben")
- (function(name) {cat(name,"\n")})("Ben")
- (function(name) {invisible(name)})("Ben")

6.2- Is there a difference between

- name <- function(name) name and name <- function(name) {name}
- name <- function(name) {name} and name <- function(name) {return(name)}
- name <- function(name) {name} and (function(name) {name}) -> name

6.3- Upon execution, is there a difference between name() and name("Peter") when

- name <- function(name="Peter") name
- name <- function(name="Peter") name2 <- name

For these two declarations of the function name(), is there a difference in the type of the R object res given by res <- name("Ben")?

6.4- What R object is returned upon execution of name() when:

name <- function(name="Peter") {
  name
  # The last instruction is a comment!
6.5- When name <- function(firstname="Peter",name="L") {
  paste(firstname,name) }, what R object is returned by
  • name(firstname="Ben")
  • name(fir="Ben")
  • name(n="D",f="R")

6.6- Rewrite the following function declaration in one line, without using the com-
  mand separator ";":
  name <- function(name) { if(missing("name"))
  name <- "Peter"; cat(name,\n) }

6.7- What is the output of the execution of names("peteR","Ben","R") when:
  • names <- function(...) c(...)
  • names <- function(...) list(...)
  • names <- function(...) for(name in c(...)) print(name)
  • names <- function(...) for(name in list(...)) print(name)

Same question upon execution of
  names(c("peteR","L"),c("Ben","L"),c("R","D"))

6.8- When names <- function(names=c("Ben","R"),...) c(names,...),
  which R objects are returned by names("PeteR"), names(name="PeteR")
  and names(names="PeteR")?

Same question when
  names <- function(...,names=c("Ben","R")) c(names,...).

6.9- Create a constructor function Male() generating an object of class "Male"
  with fields firstname and name (in an object of type list). Create the
  method hello.Male() which displays "Hello Mister FIRSTNAME NAME!"
  (do not forget the "\n" at the end of the display!) for an object with val-
  ues "FIRSTNAME" and "NAME" respectively for the fields firstname
  and name. When man <- Male("Ben","L"), what is produced upon execution
  of the following commands: hello.Male(man) and hello(man)? What
  code should you execute in addition for the two results to be identical?

6.10- Create the analogous functions for the class "Female" (hint: do not forget to
  update the gender in hello.Female()). When
  woman <- Female("Elsa","R"), what is produced upon execution of the
  following commands: hello.Male(woman), hello.Female(woman) and
  hello(woman).

6.11- When welcome <- function(...) for(person in list(...)){
  hello(person)}, what is returned by welcome(man,woman)?
  And when welcome <- function(...) for(person in c(...)){
  hello(person)}?

Same question when hello.default <- function(obj){
  cat("hello",obj,"!\n").
Worksheet

Programming functions and object-oriented programming in R

Before reading the practicals of this chapter, we strongly advise you to revise those of the previous chapters (especially the one on “advanced plots”) and to reorganize the solutions to the exercises in as many functions as necessary.

A- Managing a bank account

The aim of this practical is to create three minimalist functions to manage bank accounts. The accounts will be stored in data.frame objects all called accounts and stored in different .RData files. All these files will be located in the same folder. The path to this folder should be saved in the R variable .folder.accounts and be accessible in all the functions you develop.

6.1- The instruction file.path(.folder.accounts,paste(name,".RData", sep="")) gives the path of the file associated with the account Name. Create the functions path.account(), which takes one formal argument name (representing the name of the account) and returns the complete path to the file (which contains the object account of class data.frame) with extension .RData.

6.2- Given that factor(levels=c("Debit","Credit")), numeric(0) and character(0) respectively give empty vectors of explicit types, which expression would generate an empty data matrix with the predefined fields amount, mode, date and remark? Create the function account() (not to be confused with the variable account called in its body) which takes one argument name and creates a new account.

6.3- Create the functions debit() and credit() to respectively debit and credit an amount amount (second argument) from the account name (first argument). The third argument is any comment to put as remark. A fourth argument can represent the date; the default value is format(Sys.time(),"%d/%m/%Y") (i.e. the date of input). Remember to use the functions load() and save() to load and save the variable account in the body of each function.

6.4- If account is the data matrix containing information on the account, what is returned by sum(account[account$mode=="Credit","amount"])? Modify the function account() so that it returns the current state of the account only when the file returned by path.account(name) exists (use the function file.exists() to test whether a file exists).

6.5- Complete account management by creating any additional functions you wish.
6.6- **Optional question:** Since most use of R is done with objects, adapt the previous functions in a way that respects the R object-oriented philosophy. You can use the next practicals for inspiration.

B- Organizing graphical objects

When you think about it, plots in R do not really respect the object-oriented spirit: unlike most other entities, an R plot is not considered as an object which can be saved (and possibly modified) and on which certain methods can be applied. We shall attempt to propose a very basic prototype to draw a plot with circles and rectangles (and hence squares). You can enrich this library with graphical objects as you wish. Our aim is to maintain a list of graphical objects, with the possibility of changing any of its elements at any time.

6.1- R functions `plot.new()` and `plot.window()` are used to initialize a plot. The argument `asp` set to 1 creates plots with correct units for the x and y axes. Propose an object `Window` which gives the user the option of saving the dimensions of the graphics display window. The user can then call the constructor function (or method) `Window()` (which could have the same name as the class), which takes as arguments `x` and `y` (the coordinates of the centre), `width` and `height` (dimensions along the x and y axes respectively) and optionally `log` (logarithmic transformation). All these quantities should be stored in an object list, returned by the constructor function `Window()`, after affecting its class to "Window".

6.2- Similarly, propose constructor functions for objects of classes `Circle` and `Rectangle`. The fields `x` and `y` represent the coordinates of the centre of the object, `radius` is the radius of a circle and `width` and `height` are the dimensions of a rectangle.

6.3- Propose plotting methods `plot.Window()`, `plot.Rectangle()` and `plot.Circle()`. You can find inspiration in the following R treatments used to display a new plot with a circle and a square centred at the origin and of diameter and side length set to 1:

```
plot.new()
plot.window(xlim=c(-1,1), ylim=c(-1,1), asp=1)
rect(-.5,-.5,.5,.5)
symbols(0,0,circle=.5,inches=FALSE,add=TRUE)
```

6.4- Test the code you have developed by executing the code:

```
mywindow <- Window(0,0,2,2)
mycircle <- Circle(0,0,.5)
myrectangle <- Rectangle(0,0,1,1)
plot(mywindow);plot(mycircle);plot(myrectangle)
```

If all goes well, you should see a graphics window with a circle inside a square.
6.5- We now need to develop the methods associated with the class `MyPlot` which will contain the list of all graphical objects. First, propose a constructor function `MyPlot()` which initializes an object as `list(objects=list())` (where `objects` is the field containing the list of graphical objects), affects the class "MyPlot" and returns the object.

6.6- Propose a method `add.MyPlot()` which adds graphical objects. Remember to give a generic function `add()` to launch all associated methods. Use the functionalities of the list of supplementary arguments ... and the function `c()` so that the method `add.MyPlot()` can initialize as many graphical objects as the user wishes. Propose a method `plot.MyPlot()` which executes the methods `plot()` for all graphical objects. The user can then enter the following lines to get the same result as earlier:

```r
myplot <- MyPlot()
myplot <- add(myplot,Window(0,0,2,2),Circle(0,0,.5),
              Rectangle(0,0,1,1))
plot(myplot)
```

6.7- To display a plot, you need to initialize an object of type `Window` and put it in first position of the list of graphical objects of the class `MyPlot`. It might be useful to initialize it directly inside the constructor function `MyPlot()`. The arguments of the function `Window()` can be proposed directly for the function `MyPlot()`.

```r
myplot <- MyPlot(Window(0,0,2,2),Circle(0,0,.5),
                 Rectangle(0,0,1,1))
plot(myplot)
```

However, note that in the first line, it is assumed that the default values of the arguments of the function `Window()`, `Circle()` and `Rectangle()` are appropriate.

6.8- The project is launched with this first prototype. You can complete it as you wish. If you need inspiration, you could try managing the list of graphical objects (for example, deleting or modifying an object), display styles, axes...

C- Creating a class `lm2` for linear regression with two regressors

The aim of this practical is to reproduce the procedure used by our two friends for simple regression. Graphical display will be made possible by the excellent package `rgl`, which is an OpenGL interface for R. Given the technical difficulty of this chapter, we propose here to develop functions (actually methods). Given that some aspects are very technical, the aim is only to get the reader to understand all the development steps of the following functions. This practical is aimed at more advanced users.
The following function returns an object of class `lm2` which inherits from the standard class `lm`.

```r
lm2 <- function(...) {
  obj <- lm(...)
  if(ncol(model.frame(obj))!=3)
    stop("two independent variables are required!")
  class(obj) <- c("lm2",class(obj)) # or c("lm2","lm")
  obj
}
```

For example, execute the following commands:

```r
> n <- 20
> x1 <- runif(n,-5,5)
> x2 <- runif(n,-50,50)
> y <- 0.3+2*x1+2*x2+rnorm(n,0,20)
> reg2 <- lm2(y˜x1+x2)
> summary(reg2)
```

```
Call: lm(formula = ..1)
Residuals:
       Min        1Q    Median        3Q       Max
-32.0767  -17.1529   0.9872  12.3298  35.5909
Coefficients:
              Estimate Std. Error t value Pr(>|t|)
(Intercept) -1.8708   5.0769  -0.368 0.7170
   x1         2.8400   1.9594   1.449 0.1649
   x2         1.8084   0.1952   9.263 4.7e-08 ***
---
Signif. codes:  0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
Residual standard error: 21.14 on 17 degrees of freedom
Multiple R-squared: 0.848,    Adjusted R-squared: 0.8301
F-statistic: 47.42 on 2 and 17 DF,  p-value: 1.112e-07
```

No surprises here: the R output of the summary is given by the method `summary.lm()`.

The user now wishes a 3D scatter plot with the regression plane given by the standard method of least squares.

```r
plot3d.lm2 <- function(obj, radius=1, lines=TRUE, windowRect, ...)
{
  matreg <- model.frame(obj)
  colnames(matreg) <- c("y","x1","x2")
  predlim <- cbind(c(range(matreg[,2])),
                   rev(range(matreg[,2])))
  rep(range(matreg[,3]),c(2,2)))
  predlim <- cbind(predlim,apply(predlim,1,
                   function(l) sum(c(1,l)*coeff(obj))
                   ))
  if(missing(windowRect)) windowRect=c(2,2,500,500)
  plot3d(matreg, predlim, 
          radius=radius, lframes=lines, windowRect=windowRect)
}
```
Here is a direct application of this method with four graphical illustrations for four different viewing angles.

```r
> require(rgl)
> plot3d(reg2)
```
Chapter 7
Managing sessions

Prerequisites and goals of this chapter

- Reading previous chapters.
- This chapter describes various procedures to manage R sessions. You have to follow a rather rigorous discipline and a methodology specific to R to make sure you save your work efficiently. We present the commands to save your work: objects you have created, instructions you have typed, plots you have drawn. We also present a few other useful commands and offer a short introduction to package creation.

SECTION 7.1
R commands, objects, and storage

- Storing objects

The basic commands are either expressions, or affectations using the arrow <- or ->. If an expression is typed in, it is evaluated, the result is displayed and then lost. An affectation also evaluates an expression, but does not necessarily display the result. The result is then stored in an object.

\[
\begin{align*}
> 2+9 & \quad \text{The result is displayed then lost.} \\
& \quad \text{[1] 18} \\
> \text{My.Weight} <- 75 & \quad \text{My.Height} <- 1.90 \quad \text{These two results are stored. They can be re-used.} \\
> \text{My.BMI} & <- \text{My.Weight}/\text{My.Height}^2
\end{align*}
\]
• Listing objects

After you have created R objects, you can get the list of all objects with the function `ls()` or the synonymous function `objects()`.

```r
> ls()
[1] "A" "B" "cl" "clus"
[5] "combnRC" "combnRCF" "corr" "decision"
[9] "e" "inv" "lm2" "lsq"
[17] "myfunc" "n" "nbclus" "out"
[21] "plot3d.lm2" "pmvtRCR" "reg2" "space"
[25] "space2" "space3" "x1" "x2"

> objects()
[1] "A" "B" "cl" "clus"
[5] "combnRC" "combnRCF" "corr" "decision"
[9] "e" "inv" "lm2" "lsq"
[17] "myfunc" "n" "nbclus" "out"
[21] "plot3d.lm2" "pmvtRCR" "reg2" "space"
[25] "space2" "space3" "x1" "x2"
```

• Deleting objects

To delete objects, use the function `rm()`.

```r
> rm(My.Height) # Delete the object My.Height.
> ls()
[1] "A" "B" "cl" "clus"
[5] "combnRC" "combnRCF" "corr" "decision"
[9] "e" "inv" "lm2" "lsq"
[13] "M" "My.BMI" "My.Height" "myfunc"
[17] "n" "nbclus" "out" "plot3d.lm2"
[21] "pmvtRCR" "reg2" "space" "space2"
[25] "space3" "x1" "x2"
> rm(list=ls()) # Delete all objects in the current work environment.
> ls()
character(0)
```

Advanced users

You can use regular expressions to delete objects following a certain name pattern. For example, the following instruction only deletes objects with a name of the form a?b, where ? represents a single character:

```r
rm(list=ls(pattern=glob2rx("a?b")))
```

We will not give further details and refer the interested reader to the online help for the function `glob2rx()`.
When working with R, objects are created: vectors, matrices, functions, etc. These objects are physically saved in a file on the hard disk called **workspace**. The file name extension must be `.RData` (or `.rda` in older versions of R).

It is possible (and highly advisable) to create several `.RData` files: one for each project you are working on. You should create these `.RData` files in different appropriate folders. For example, suppose you are working on two different statistical projects: one related to cars and one related to climate events. You could then create a folder called `Cars` containing a file `cars.RData`, and another folder called `Climate` containing a file called `climevt.RData`; these files will contain the R objects corresponding to the two studies.

The function `save.image()` is used to save a workspace; you can use the function `load()` to load an existing workspace. Under Microsoft Windows, you can access `.Rdata` files from the menus File/Save workspace... and File/Load workspace. Under Macintosh, you can access .Rdata files from the menus Workspace/Save workspace file and Workspace/Load workspace file. The menu Workspace is also useful to explore the contents of the workspace (you can open a window with a list of all objects including their type and dimension) and to edit objects.

Note that the function `save()` will save only the objects you choose in the workspace.

Note

There is a default workspace in R. To find the path to the folder where it is stored, type the instruction `getwd()` just after launching R.

It is worth noting that the command `getwd()` returns the current working directory. The command `setwd()` is used to change working directory.
Start R then type:

```r
x <- 3 # Assigning a value to x; check the contents of x.
x <- 4 # Assigning a new value to x, overwriting the old value.
```

Now, outside of R, create two folders in the same directory: one called Cars, the other Climate. Then type into R the following instructions:

```r
rm(list=ls()) # Start by deleting all objects in the current workspace.
ls() # Returns character(0), indicating that no objects are left.
x<-c("FIAT","VOLVO","RENAULT","PEUGEOT") # Assign a value to x.
ls() # Return x.
setwd("/path/to/Cars") # Move to folder Cars.
save.image("cars.RData") # Create the file cars.RData # in the folder Cars.

You have created an object called x, containing a list of car manufacturers. This object is saved (in binary form) in the workspace cars.RData in the folder Cars.

Now, type the following instructions:

```r
# Affect a new value to x:
x <- c("storm","hurricane","tornado","typhoon")
setwd("/path/to/Climate") # Move to folder Climate.
save.image("climevt.RDat") # Create the file climevt.RDat # in the folder Climate.

You have created an object called x containing names of climate events. Note that the old value of x has been overwritten in the current workspace. This new object x is saved in the workspace climevt.RDat in the folder Climate. Exit R (you can use the function q("yes")), Start R again and type in the following instructions:

```r
ls() # Returns x; check the value of x
load(file.choose()) # Open the file cars.RData # in the folder Cars.
ls() # Returns x; check the value of x.
load(file.choose()) # Open the file climevt.RDat # in the folder Climate.
ls() # Returns x; check the value of x.
q("no") # Exit R.

This shows the point of having several workspaces: you can keep several objects which have the same name but contain different information. Otherwise, the second affectation of a value to x would overwrite the first!
When exiting R with the command `q()` (or by clicking the cross at the top right corner of the R window under Windows, or on the red button at the top left corner for Macintosh users), the following question is asked:

**Save an image of the session?**

If you answer Yes (or `y` under Linux), a workspace file called `.RData` (containing all objects created during the session) and a command history file called `.Rhistory` (which we explain in the next section) are saved in the current directory.

---

The function `attach()` plays a similar role to the function `load()`. The difference between these two functions is explained later on.

---

**SECTION 7.3  Command history: .Rhistory files**

R includes a mechanism to recall and reexecute old commands. The up and down arrows on the keyboard can be used to go back and forward in the command history. Once you have located a command using this method, you can move the cursor using the right and left arrows, delete characters with the DEL key, and add or modify characters with the keyboard.

Just like all objects can be saved in a dedicated file with the command `save.image()`, you can also save all commands you typed. The commands are saved in a file which must have the extension `.Rhistory` (or `.rhi` in old versions of R).

Here again, it is a good idea to save a `.Rhistory` file for each project you are working on. You can then access these commands in an interactive fashion from the R command line, using the keyboard arrows.

To save the command history of the current session, use the command `savehistory()`. To load the command history from a previous session, use the command `loadhistory()`. Under Microsoft Windows, the same operations can be done from the menus File/Save History... and File/Load History...
Mac

Mac users can rely upon R.app which offers a lateral bar to view, navigate and manipulate the history. It is activated by clicking the icon Show/Hide history in the R console.

Tip

The command history() opens a new window with a list of all commands from the current session.

Do it yourself

Start R and type in the following instructions:

```r
Mc <- "My car"
# Use the up arrow and change the last command to:
Yc <- "Your car"
# Save a file cars.Rhistory in the folder Cars.
savehistory("/path/to/Cars/cars.Rhistory")
q("no") # Exit R.
# Open R again.
# Note that the up arrow does not
# give access to the last two commands.
# Open the file cars.Rhistory in the folder Cars.
loadhistory(file.choose())
# Now, the up arrow can be used
# to find old commands.
q("no")
```

SECTION 7.4

Saving plots

You might also want to save plots you have produced with R. The instructions listed in this section have already been introduced in Chapter 5, but we give them again as a matter of interest. For example, to save the following plot:

```r
> curve(cos(x),xlim=c(-10,10))
```
you simply need the command:

```r
dev.print(png, file="myplot.png", width=480, height=480)
```

Another way of saving a plot is to first redirect the graphical device to a file, then execute the command to generate the plot.

```r
png(file="myplot2.png", width=480, height=480)
curve(cos(x), xlim=c(-10,10))
dev.off()
```

**Warning**

Remember to use the function `dev.off()` at the end of the procedure: it closes the device and writes the plot to a file. Otherwise, the file will remain empty.

Other commands are available to save images in other formats: `jpeg()`, `png()`, `bitmap()`, `postscript()`, `pdf()` ...

Under Microsoft Windows, you can also use the menu File/Save as..., or copy-paste the plot to another software. You must first click on the graphics window to make it active.

**Mac**

You can use the menus File/save. The saved/copied plot is in the PDF format. Note that graphical windows have a “history”. You can explore the history of generated plots with the keystroke combination COMMAND + left and right keyboard arrows.
A package is a collection of data and functions belonging to a same theme.

When you install R, some basic functionalities come out of the box. But you can extend the functionalities of R by adding libraries, also called packages. First, install the package on the computer’s hard disk, then load (activate) it in the memory of R only when needed (see Appendix A for further details).

First, you can use the function `search()` which gives the list of databases (collections of R packages) attached to the system. The function `searchpaths()` returns the same list, but adds the path to the corresponding file.

Recall that the function `library()` returns the list of all packages available in the library `C:/PROGRAM FILES/R/R-2.14.0/library`.

**Do it yourself**

```
search()  # Return the list of databases attached to the system.
library()  # Return the list of packages saved on the disk.
```

Install package R2HTML and type in the following instructions:

```
library()  # Package R2HTML is present on the disk.
search()  # Package R2HTML is not loaded.
require(R2HTML)  # Activate package R2HTML.
search()  # Package R2HTML is now loaded.
```

**Note**

The instructions `require(package)` and `library(package)` have a similar behaviour. The function `require()` first checks whether the package is already loaded (activated). If it is, then it will not be reloaded. In this sense, this function is thus more efficient than the function `library()`.

**SECTION 7.6**

Managing access paths to R objects

In the previous section, we saw the use of the function `search()`, which lists and numbers all databases attached to the system. We also saw how to load a package with the function `require()`. A database can also be attached with the function
attach(), and detached with the function detach(). These two functions will be put to use in the practicals at the end of this chapter.

Tip

Suppose you have created a data.frame (individuals×variables table) called mydata. Then attach(mydata) attaches the data.frame mydata, giving access to the variables of the data.frame data directly by typing their names in the console.

The following instructions will help you understand how the function attach() works.

```
# Start R.
attach(file.choose()) # Open the file cars.RData from the folder Cars.
ls() # x is not mentioned.
x # This is strange: the contents of x are displayed, 
   # yet ls() does not mention it.
rm(x)
Warning message:
In rm(x): variable "x" cannot be found.
x # Yet x is there!
```

The command `ls(pos=n)`, where `n` is an integer, returns the list of objects in the database at the `n`th position in the list given by `search()`.

For example, `ls(pos=2)` returns the objects for the module in second place `ls(pos=3)` for the module in third place, and so on.

Note that position 1 is reserved. Thus `ls()` is equivalent to `ls(pos=1)` and gives the list of all objects in the current workspace.

```
search()
ls(pos=2) # List all objects from the database cars.RData.
```
require(datasets) # Load several datasets.

warpbreaks
mydata <- warpbreaks
fix(mydata) # Read the data and the variables names.
breaks # Returns an error message: this object
# is not defined.
search() # Returns the list of databases attached
# to the system.
searchpaths() # Same list, with the complete path.

position <- match("package:datasets",search())
# Get the position of datasets in the list
# output by search().

ls(pos=position) # Gives the list of all objects in datasets.

data() # Description of these datasets.

attach(mydata)
search()
searchpaths()

ls(pos=2)
breaks # No error message.

We now have direct access to the columns of mydata: breaks, wool and tension.

### Other useful commands

In this section, we introduce a few other interesting commands to manage your work:

- Under Microsoft Windows, the menu File/Save to file... can be used to save to a text file all the text displayed in the console (including error messages); by default, the file is called lastsave.txt and is created in the current directory. The size of the contents is limited by parameters which can be changed in the menu Edit/Preferences...;

- The function `sink(file="myoutput.txt")` redirects all R output (which would usually be displayed in the console) to the file myoutput.txt. To stop this functionality, type `sink()` in the console;

- The menu File/Source R code... is used to transfer a sequence of R instructions from a file directly to the console. This command also checks the syntax of the R code in the file before transferring it. Equivalently, you can type `source(file.choose())` in the console;
7.8 Problems in memory management

\* R includes many functions to manage files and directories on the hard disk: file.create(), file.exists(), file.remove(), file.rename(), file.append(), file.copy(), file.symlink(), dir.create(), Sys.chmod(), Sys.umask(), file.info(), file.access(), file.path(), file.show(), list.files(), unlink(), basename(), path.expand(). For example, the command list.files() returns a vector of strings of characters of the names of files in the specified directory. The command file.exists() is used to find out whether a file exists in a given directory. We refer the reader to the help files for the details of all these functions.

### SECTION 7.8

\* Problems in memory management

In this section, we shall focus on memory management by the computer in general and by R in particular. We shall try to understand why messages occur such as:

cannot allocate a vector of size xxx

We shall also see how to work with high dimension vectors and matrices.

Before giving indications on memory management in R, we need to give a short explanation of the internal workings of a computer. Upon execution of an R program, the following internal components of the computer are used:

- the hard disk (which contains the code and data files);
- the processor (which performs the calculations; there are 32 bit and 64 bit processors);
- and the RAM (for Random Access Memory), which holds temporarily the data which are used by the processor for the calculations.

In what follows, we shall mostly focus on the RAM, though we will also mention the processor. The main interest of the RAM as opposed to the hard disk is that it can be accessed very quickly. In a computer, the processor accesses the instructions of the program to execute and the data necessary to execution from the RAM.

### 7.8.1 Organisation of RAM

The RAM is organised as an ordered sequence of boxes, and each box can contain a binary digit: 0 or 1. The information contained in a box, the smallest quantity of information that can be contained, is called a bit (for binary digit). At this point, it is worth noting that information is actually often organised in blocks of 8 boxes. Another unit has thus been introduced: the byte, which is worth 8 bits.
Also note that each block is numbered; the number of an (8 box) block is called its memory address. A memory address is thus an identifier, which designates a specific zone of memory where data (or instructions to run) can be read and stored. This identifier is usually an integer, often expressed in hexadecimal notation (base $b = 16$, see section 3.9).

![Diagram of memory storage](image_url)

Fig. 7.1: Illustration of storage of values in memory. Each little box contains a binary number (0 or 1). Each green number gives the decimal representation of the number in binary form in the block above. Each red number gives the address (expressed here in decimal notation) of the 8-box block above. Note that the same memory addresses could have been written in hexadecimal notation ($b = 16$), giving 3C, 3D, 3E and 3F.

### 7.8.2 Accessing the memory

A process running on a computer does not usually have a direct access to the RAM, but rather to the so-called virtual memory. The memory addresses used by R are thus addresses in the virtual memory; the operating system then puts these addresses in correspondence with the actual RAM memory addresses. We do not distinguish between the two types of memory.

To access a given zone of memory, R uses (in a transparent way hidden from the user) what is called a pointer (a quantity which “points” to the desired memory zone). A pointer is a variable containing a memory address. At the address contained in a given pointer, we can find for example a data point. Note that each data point has a specific type, such as integer, double, etc. (see chapter 1). Note also that an integer is coded on 4 bytes, a double on 8 bytes, a character on 1 byte, a logical on 4 bytes, a complex on 16 bytes, to cite the most common variable types. This is
true on a 32 bit processor and on a 64 bit processor. Examine now the following R instructions:

```r
> x <- 3L # create the value 3, of type integer,
> # or equivalently:
> x <- as.integer(3)
```

Given what we just explained, we can assume that at the same time, a memory slot of 32 successive blocks (4 bytes of 8 bits each) is reserved (or allocated), and a pointer is created containing the address of (the first of) these boxes. In fact, the pointer must not only contain the address of variable \( x \), but also its type to know over how many boxes the variable is stored. For this reason, the pointers are said to be “typed”. When a typed pointer is incremented (i.e. when we need to add one unit to the address it contains), it is not necessarily incremented by 1, but by the size of the pointed type.

Fig. 7.2: Illustration of R storage in memory of a (signed) integer. Each little box contains a binary digit (0 or 1). The green number gives the decimal notation of the integer expressed in binary notation in the four blocks above. The red number gives the address (expressed here in decimal base) of the first 8-box memory block above. Note that here, a number is stored over 32 boxes, and not over 8 as in figure 7.8.1. Furthermore, the first box is used to specify the sign of the number, negative here.

### 7.8.2.1 Problems caused by memory management of integers

Since a (signed) integer is coded over 4 bytes, i.e. 32 bits, the largest integer that can be represented is 2147483647. Indeed, if the first bit is reserved for the sign, there are 31 remaining available boxes, or \( 2^{31} \) possible arrangements. Counting 0, the largest available integer is thus \( 2^{31} - 1 \), or:

```r
> as.integer(2^31-1)
[1] 2147483647
> .Machine$integer.max
[1] 2147483647
```

The result above is thus not surprising.

```r
> as.integer(2^31)
[1] NA
```

The number \( 2^{31} \) can thus only be handled by R as a double:

```r
> 2^31
[1] 2147483648
```
> is.double(2^31)
[1] TRUE

The largest vector that can be allocated in R is of length \(2^{31} - 1 \sim 2 \times 10^9\), whether on a 32 bit or 64 bit processor. This is easy to understand: it corresponds to the largest integer that R can define, and the length on a vector (number of elements) is stored as a (signed) integer.

We note in passing that this knowledge on R’s behaviour helps understand the output below.

> 46360*46360 # 46360 is stored as a double.
[1] 2149249600
> 46360L*46360L # 46360L is stored as an integer.
[1] NA
> sum(1:304) # 1:304 is stored as an integer.
[1] 46360
> sum(1:304)*sum(1:304)
[1] NA

Warning message: In sum(1:304) * sum(1:304) : NA produced by overflow
> 46360^2 # The result is stored as a double.
[1] 2149249600
> sum(1:304)^2 # The result is stored as a double.
[1] 2149249600

The Warning message above comes from the fact that sum(1:304) is an integer. Note that the exponent function (\(^\)) transforms its arguments into reals and returns a real number.

### 7.8.2.2 Successive allocation of memory

In fact, the smallest block of memory that can be allocated (reserved) by R is 8 bytes (=64 bits). Memory is thus allocated in R in blocks of 8 successive blocks (both on 32 and 64 bit processors). In the instruction \(x \leftarrow 3L\), there are thus 64 reserved boxes (of 1 bit each), of which the first 32 are used to store the integer value +3. All 64 boxes would be used to allocate a double, with the instruction:

> x <- 3.0

The 64 boxes are apportioned as follows: 1 box for the sign, 11 boxes for the exponent and 52 boxes for the significand, in the floating point representation (see section 3.9.2).
The package associated with this book includes the functions `getaddr()` and `writeaddr()` which can be used respectively to get the memory address of a variable containing a number, and to write a value at a memory address.

```r
> x <- c(8L, 9L)
> x
[1] 8 9
> addr <- getaddr(x)$addr.int # Gets the address of the first box of the 64-box block where x is stored.

> addr
[1] 53173920
> writeaddr(addr, 6L) # Write the integer 6 at this address
> x
[1] 6 9
> writeaddr(addr+4L, 7L) # An integer is coded over 4 bytes, hence increment the address by 4 to get to x[2].

> x
[1] 6 7
```

Now with a vector of doubles:

```r
> x <- c(12.8, 4.5)
> x
[1] 12.8 4.5
> addr <- getaddr(x)$addr.int # Get the address of the first box of the 128-box block where x is stored.

> writeaddr(addr, 6.2)
> x
[1] 6.2 4.5
> writeaddr(addr+8L, 7.1) # A double is coded over 8 bytes.
> x
[1] 6.2 7.1
```

Advanced users

R can only access memory boxes that have been allocated by R, and other software cannot access the memory zones reserved by R. This is essential! Otherwise, the data for our calculations could be modified by external software. Even another R session cannot access the memory zones reserved by the first. For example, type in a first R session:

```r
> x <- 1L
> getaddr(x)$addr.int
[1] 37602112
```

which is the address of the memory block containing the integer value 1. Then type in a second R session:

```r
> writeaddr(37602112, 7L)
```
Then (if the second R session does not crash!) we can check that the value of \( x \) in the first session has not been modified. Return to the first session and type:

\[
> x \quad \text{# The attempt to modify the value of } x \text{ in another R session}
\]

\[
\begin{array}{l}
\text{# is doomed to failure.} \\
[1] 1
\end{array}
\]

\[
> \quad \text{# Try the modification in the same session:}
\]

\[
> \text{writeaddr}(37602112,7L)
\]

\[
> \quad \text{# This time it works!}
\]

\[
> x
\]

\[
[1] 7
\]

### 7.8.3 Object size in R

A useful R function gives the size of an object: the function `object.size()`. Given the previous subsection, we expect the instruction `object.size(3L)` to output 8 bytes, but that is not the case.

\[
> \text{object.size(3L)} \quad \text{# (On a 64 bit processor.)}
\]

```
48 bytes
```

In fact, each R object contains (even when declaring a simple integer by `x <- integer(3)`) a header which takes up some space in the RAM: 24 bytes on a 32 bit processor and 40 bytes on a 64 bit processor. This header is used to save information of the created object: its type (`integer`, `double`, `complex`, etc ..), its length, etc ..

**Tip**

To find out on what kind of processor R is running, use the instruction:

\[
> \text{.Machine$sizeof.pointer}
\]

```
[1] 8
```

The value 8 is returned for a 64 bit processor and the value 4 for a 32 bit processor.

The values returned by the following instructions are rather clear now:

\[
> \quad \text{# On a 32 bit processor:}
\]

```
> object.size(3L) - 24
8 bytes
```

\[
> \quad \text{# On a 64 bit processor:}
\]

```
> object.size(3L) - 40
8 bytes
```
Memory allocation in R is done differently for small and large integer vectors. Small vectors belong to one of 6 classes, depending on their length (lesser than or equal to 2, 4, 8, 12, 16 or 32), and can store data of 8, 16, 32, 48, 64 or 128 bytes respectively. Since an integer uses up only 4 bytes, these classes can be used to store respectively 2, 4, 8, 12, 16 and 32 integers. An integer vector of length \( n > 32 \) uses up space of size \( 4n + 40 \) if \( n \) is even and \( 4(n + 1) \) if \( n \) is odd, to which we add a header of 2 bytes on a 32 bit processor and 40 bytes on a 64 bit processor. The following code returns the size in memory of vectors of increasing size.

```r
> N <- 50
> V <- vector(length = 50)
> for (L in 1:N) {
+   z <- sample(N, L, replace = TRUE)
+   V[L] <- object.size(z)
+ }
> V - 24 # On a 32 bit processor.
[1] 8 8 16 16 32 32 32 32 48 48 48 48 64 64
[29] 128 128 128 128 136 136 144 144 152 152 160 160 168 168
[43] 176 176 184 184 192 192 200 200
> V - 40 # On a 64 bit processor.
[1] 8 8 16 16 32 32 32 32 48 48 48 48 64 64
[29] 128 128 128 128 136 136 144 144 152 152 160 160 168 168
[43] 176 176 184 184 192 192 200 200
```

### 7.8.4 Total memory used by R

The total size of virtual memory allocated to R in a session includes:

- memory used to store the values of objects (their contents);
- memory used to store the headers of objects.

This information can be accessed with the function `gc()`, in which `Ncells` represents the number of cells used for the header, and `Vcells` the number of blocks for the values.
The following example illustrates this function.

```r
> rm(list=ls()) # Delete all objects in the session.
```

Type three times `gc()`. Note that the values displayed stabilize. Now type the instruction:

```r
> x <- as.integer(3)
```

Type several times `gc()` until the results stabilize. Note that the value of `Vcells` has increased by 1 unit, corresponding to 8 bytes (smallest possible size of a block of data). Recall that an integer needs 4 bytes but is still stored in a memory zone of 8 bytes.

The total amount of memory available to R depends on several factors:

- the RAM physically present on the computer;
- the RAM already used by the operating system and the other software being run on the system (such as a web browser if it is open);
- the type of processor (32 or 64 bits), since the RAM is limited to 4 GB (1 GB = 1024 kB) for 32 bit processors (and it is often closer to 3 GB or 2 GB), but is (really!) much larger for 64 bit processors.

Note

On a 32 bit processor, an address is coded over 32 bits, hence the addressable memory is limited at $2^{32}$ bytes (=4 GB). On a 64 bit processor, an address is coded over 64 bits, so theoretically, the addressable memory is “limited” at $2^{64}$ bytes, a huge number. In fact, it is usually limited by the processor’s architecture. This information can be obtained from the manufacturer (it is called ‘Max Memory Size’).

Note also that R allocates memory for the creation of large objects, and clears these objects from memory (when they are no longer used) by a process called garbage collection. You can force garbage collection with the function `gc()`.

Warning

When creating a large object, the memory reserved by R must be contiguous (it cannot be fragmented in several blocks).

It is therefore possible that there remains enough total memory for R, but no “gap” large enough to fit the data of a single large object. Here is an illustration.
Beware that these commands may provoke a major slowdown of your system, or even a brutal crash of R.

```r
> # First, type the instructions:
# rm(list=ls()); gc(); gc() # to empty the memory.
> P <- 14000
> D <- matrix(rep(0, P*P), nrow=P)
Error: cannot allocate a vector of size 1.5 GB.
> # But the next allocation is certainly possible, 
# after typing gc();gc() # to empty the memory.
> Q <- round(sqrt(P^2/2))
> D1 <- matrix(rep(0, Q*Q), nrow=Q)
> D2 <- matrix(rep(0, Q*Q), nrow=Q)
> # The sum of the sizes of D1 and D2 is approximatively 1.5 GB.
> object.size(D1) + object.size(D2)
1567843440 bytes
```

In the example above, it was not possible to create a single object of size 1.5 GB, but it was possible to create two objects of size 0.75 GB each.

### Tip

Note that on a 64 bit processor, we would probably not have encountered this issue, even when creating an objects of size close to 3GB:

```r
> # First we typed the instructions
# rm(list=ls()); gc(); gc() # to empty the memory.
> P <- 20000
> D <- matrix(rep(0, P*P), nrow=P)
> object.size(D)
3200000200 bytes
```

### 7.8.5 A few recommendations

An elementary understanding of memory management on a computer in general, and in R in particular, will be very useful to help identify the origin of memory-related issues. Our first recommendation is thus to read the previous sections. We give here some extra recommendations.

For example, you could calculate the (approximative) size of a matrix before creating it. Since a real number uses up to 8 bytes, a real-valued matrix of size $n \times p$ needs $8np$ bytes. If you need to work with very large matrices, a 64 bit processor will allow you to allocate larger memory blocks. Compare this to a 32 bit processor which will usually not allow for more that 2 gigabytes. If you are not able to create a large object, remember to remove (using the function `rm()` other useless large objects (the function `object.size()` gives the size of such objects) and to free up some memory with the function `gc()`.

You can also close other software running...
on your computer to free up some memory, and as a last resort purchase further physical memory.

**Linux**

The software *ksysguard* can be used to visualize in real time the memory used by *R* and by the other processes on your system.

Another option would be to split your matrix into several submatrices and find a way to perform your analysis on those, before combining the results.

**Tip**

The packages *bigmemory*, *ff* and *RevoScaleR* may be useful.

Under Windows, the functions `memory.size()` and `memory.limit()` display some information on the memory used. You can also read the online help: `help("Memory-limits")`.

**Note**

These problems, which stem from the conception of *R*, may be solved in the future. We refer the interested reader to the document http://www.divms.uiowa.edu/~luke/talks/uiowa11.pdf.

### SECTION 7.9

† **Using R in BATCH mode**

It is possible to launch a sequence of *R* instructions in BATCH mode. In this mode, *R* starts and automatically executes the instructions in the background, then closes down when the work is done.

- To start this mode, use the following instruction in a DOS window (or a terminal window under LINUX or Mac):

  ```
  R CMD BATCH myfile.R myoutput.out
  ```

  The file `myfile.R` should contain the list of *R* instructions to execute and the file `myoutput.out` will contain any messages and output displayed by *R*.

**Warning**

Note that you will have to set the PATH system variable to contain the path to the executable *Rgui.exe*. See the Warning frame on page 229.
This mode is also useful when you want to start simulations on a remote UNIX/LINUX station (through a simple ssh tunnel). In this case, you should add the LINUX command `nohup`.

```
nohup /path/to/executable/R CMD BATCH myfile.R myoutput.out &
```

**Linux**

Under Linux, to find the `/path/to/executable/R`, you need to type in a terminal the instruction: `which R`.

It is also possible to create an R script that can be run without having to open R at first. To do this, download and modify to suit your needs the file `http://biostatisticien.eu/springeR/runthis.bat`.

See also

The interested reader can consult with profit the web page `http://cran.r-project.org/contrib/extra/batchfiles`.

**Linux**

Under Linux, create a script named `runthis` and make it executable (`chmod u+x runthis`). This script will contain the following lines:

```
#!/bin/bash
R --vanilla "EOF" # Pipe all subsequent lines into R.

########################################### Put all your R code here ####################################
X11(); plot(1:3)
require(tcltk)
tkmessageBox(message="hello")

########################################### end of R code ####################################
EOF
```

**SECTION 7.10† Creating a simple R package**

A package is a practical way of grouping datasets, functions and help files in a single structure. This structure is stored in a `.zip` file (or `.tar.gz` under Linux). Nonethe-
less, this operation is complicated under Microsoft Windows, because it requires the installation of many tools which are not present by default on this Operating System.

Specific documentation for Mac users will be made available on the website associated with this book.

You will need to install the following software:

- latest version of Rtools available here: \url{http://cran.r-project.org/bin/windows/Rtools/};
- \url{http://www.biostatisticien.eu/springeR/htmlhelp.exe};
- a complete version of Tex Live. Download the file \url{http://mirror.ctan.org/systems/texlive/tlnet/install-tl.zip} and unzip it in a temporary folder. Then double click on the file install-tl.bat in the subdirectory install-tl-*. A graphical installation interface pops open and will guide you through the installation of Tex Live.

Here is the procedure to create an R package:

- start R;
- import into the workspace the datasets and functions you want to include in your package;
- use the function \texttt{package.skeleton()} to create the structure of your package. You should give a value to the following arguments:
  - \texttt{name}: a string of characters containing the name of the package,
  - \texttt{list}: a vector of strings of characters, specifying the various objects (datasets and functions) to include in the package,
  - \texttt{path}: a string of characters containing the path to the directory where your package structure will be created;
- when you call this function, a folder is created in your current directory, containing the files and subfolders of your package. You then need to modify some of these files, as described in the file \texttt{Read-and-delete-me} which you will find in that folder;
- the last step is to create a .zip file containing the package structure. To this end, execute the following commands in an MS-DOS command window:
  - \texttt{R CMD check PackageName}
  - \texttt{R CMD build --binary --use-zip PackageName}
7.10 Creating a simple R package

Tip

If your R code calls C/C++ or Fortran functions, the files containing the source code for these functions need to be placed in a sub-directory called `src/`, located in the folder whose name is specified by the argument name of the function `package.skeleton()`.

The practical section at the end of this chapter gives an example of package creation.

Advanced users

Linux users who do not have access to Microsoft Windows but wish to build a package for that operating system can use the website http://win-builder.r-project.org/, on which the Linux-created `.tar.gz` package can be uploaded. A Windows-compatible `.zip` package is then sent by e-mail to the address given in the `Maintainer` field of file `DESCRIPTION`.
Memorandum

`ls()`, `objects()`: list all objects available in the workspace
`rm()`: delete an object
`.RData`: extension for workspace files
`save.image()`: save all created objects in a file (name.RData)
`savehistory()`: save the command history (.Rhistory file)
`load()`: load a .RData file containing created objects
`.Rhistory`: extension for command history files
`loadhistory()`: load command history
`dev.print()`: save a plot
`search()`, `searchpaths()`: list of databases attached to the system
`attach()`: attach a database
`detach()`: detach a database
`require()`: load a package present on the disk
`sink()`: redirect R output to a .txt file
`source()`: import a sequence of R instructions from a file to the console
`package.skeleton()`: create a package structure

Exercises

7.1- Name two R functions which return a list of objects in your session.
7.2- How would you delete the object `foo`?
7.3- Which R command gives the current directory?
7.4- Which R command changes the current directory?
7.5- What is the purpose of the function `save.image()`?
7.6- What are the four things you can save before closing an R session?
7.7- What is the purpose of the command history? Which keys are necessary to use it?
7.8- What is the purpose of the function `history()`?
7.9- Give the list of R instructions you would use to get a file called `myplot.png` containing a plot of the curve $y = x^2$.
7.10- When is the function `attach()` useful for a data.frame?
7.11- Which R function is used to load an R package to the memory?
7.12- What is the purpose of the function `source()`?

Worksheet

Managing and creating packages

A- Using the functions `attach()` and `detach()`

7.2- Display the names of the variables of the data.frame.

7.3- Type GENDER. What do you observe?

7.4- Type ls(). Can you see the variable GENDER?

7.5- Use the function attach() on your data.frame, then type GENDER. What do you observe now?

7.6- Type ls() again. What do you observe?

7.7- Use the function search() to find the position at which your data.frame is attached.

7.8- Use the argument pos of the function ls() to list the objects present at this position.

7.9- Detach your data.frame and check (using the function search()) that it worked. Now type GENDER again and observe that this object has disappeared.

7.10- Create an object called GENDER containing the string "Male". Display the contents of this object.

7.11- Use the function attach() on your data.frame then type GENDER. What do you observe?

7.12- Can you display the contents of the object GENDER of your data.frame? How about the object weight?

7.13- Type ls(). What do you observe? How about with search()?

7.14- Use the argument pos of the function ls() to check that the object GENDER of the data.frame does exist.

7.15- Use the function get() and its argument pos to display the contents of the object GENDER from your data.frame. Can you propose another approach?

B- Creating a mini-package

• Objects in the package

7.1- Start R, then change the current directory to the Windows desktop, using the instruction setwd(choose.dir()).

7.2- Create the following functions and datasets:

```r
f <- function(x,y) x+y
g <- function(x,y) x-y
d <- data.frame(a=1,b=2)
e <- rnorm(1000)
```

• Package structure

7.3- Use the function package.skeleton() to create the structure of your package.

```r
package.skeleton(name="SmallRPkg",list=c("f","g","d","e"))
```
A folder called SmallRpkg is created on your desktop. It contains three sub-folders (data, man and R) and two files (DESCRIPTION and Read-and-delete-me).

The folder data contains the files d.RData and e.RData, which contain respectively the datasets (in binary form) d and e, which you imported from the R console.

The folder R contains the files f.R and g.R, which contain the source code of the functions f and g defined earlier.

The folder man contains help files for all objects included in the package.

7.4- You must edit the help files (.Rd extension files), even if they are not empty. Use the description of the help file for the function mean in Chapter 4. The fields to fill in are made apparent in all help files by lines starting with %%. Replace those lines (including the characters %%) with the appropriate information. Do not change the sentences starting with a single %. Furthermore, in fields of the form keyword ~ kwd1, you must replace ~ kwd1 with a reserved keyword; the list of reserved keywords is given by the instruction file.show(file.path(R.home("doc"), "KEYWORDS")).

7.5- You should also change the file DESCRIPTION and fill in the relevant fields. For example, it is very important that you give a valid e-mail address.

7.6- You can then read and delete the file Read-and-delete-me.

Your package structure has now been created.

- Creating the package file

7.7- You have one final operation to perform: building the .zip file which will include your structure (modified by R). You first need to change a few system environment variables. Use the key combination WINDOWS+PAUSE to open the system properties window, go to the section System Variables and edit the variable PATH. At the beginning of this long list of semi-colon-separated paths, add the path to the executable Rgui.exe and the path to the executable hhc.exe (be careful not to delete anything!).

7.8- Open an MS-DOS command menu (using the menu Start/Execute: command) and execute the instructions

- cd "C:\Documents and Settings\johndoe\Desktop" (puts you in the folder containing the package structure).
- R CMD check SmallRpkg
  Check that there are no error or warning messages here. If there are, make the suggested changes.
- R CMD build --binary --use-zip SmallRpkg

If there were no errors, the package file SmallRpkg.zip is created.
7.10 Creating a simple R package

7.9- Install it from the following menu:

Packages/Install package(s) from zip files... Read the help files of your package.

You can follow this procedure to create more complex packages, which you can then publicize.
Part II
Elementary mathematics and statistics
Chapter 8
Basic Mathematics: matrix operations, integration, optimization

Goals of this chapter
This chapter describes basic mathematical functions. It then gives some usual operations on matrices and the most usual decompositions. We also present a few numerical integration and differentiation functions, and the main optimization functions.
The following table is an almost exhaustive list of classical mathematical functions.

<table>
<thead>
<tr>
<th>R name</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>%%</td>
<td>Remainder of the division of x by y</td>
<td>10%%3</td>
<td>1</td>
</tr>
<tr>
<td>ceiling()</td>
<td>Smallest integer greater than or equal to x</td>
<td>ceiling(2.3)</td>
<td>3</td>
</tr>
<tr>
<td>floor()</td>
<td>Largest integer smaller than or equal to x</td>
<td>floor(2.3)</td>
<td>2</td>
</tr>
<tr>
<td>round()</td>
<td>Round the value of the first argument to the number of digits specified by the second argument</td>
<td>round(2.375,2)</td>
<td>2.38</td>
</tr>
<tr>
<td>signif()</td>
<td>Round the value of the first argument to a given number of significant digits</td>
<td>signif(2.375,2)</td>
<td>2.4</td>
</tr>
<tr>
<td>trunc()</td>
<td>Integer part of x, obtained by removing all digits after the decimal separator</td>
<td>trunc(1.37)</td>
<td>1</td>
</tr>
<tr>
<td>sign()</td>
<td>Sign</td>
<td>sign(-2)</td>
<td>-1</td>
</tr>
<tr>
<td>abs()</td>
<td>Absolute value</td>
<td>abs(-2)</td>
<td>2</td>
</tr>
<tr>
<td>log()</td>
<td>Natural logarithm</td>
<td>log(1)</td>
<td>0</td>
</tr>

Note that most of these functions can take a vector as argument.
Do it yourself

- Check numerically for a few values that the following formula is correct: \( \binom{n-1}{p-1} + \binom{n-1}{p} = \binom{n}{p} \).
- Compute the sum of the first \( n \) integers for the values \( n = 1, \ldots, 10 \). Check that this corresponds to the formula \( \frac{n(n+1)}{2} \).
- Compute the sum of the squares of the first \( n \) integers for \( n = 1, \ldots, 10 \). Check that this corresponds to the formula \( \frac{n(n+1)(2n+1)}{6} \).
- For \( \mathbf{x} = (x_1, \ldots, x_n)^T = (0.83, 0.13, -1.16, -1.14, -0.68, 0.73, -1.27)^T \), compute the value of

\[
\hat{G}_n = \frac{n}{K} g_n(m_e, \hat{\theta})^2 \quad \text{where} \quad g_n(m_e, \theta) = 1 - \gamma - \frac{1}{n} \sum_{i=1}^{n} |y_i| \log |y_i|
\]

with \( y_i = \frac{x_i - m_e}{\theta}, \quad m_e = \text{Median}(x_1, \ldots, x_n), \quad \hat{\theta} = \frac{1}{n} \sum_{i=1}^{n} |x_i - m_e|, \quad K = \frac{\pi^2}{6} - 3, \quad \gamma = 1 - \psi(2) \) (Euler’s constant) and \( \psi(\cdot) \) the digamma function. Use the function \( \text{median()} \).

Note: It is sufficient to check that the value \( \hat{G}_n \) is greater than the critical value \( \text{qchisq}(1-\alpha, \text{df}=1) \), for a given level \( \alpha \) (usually 5%), to decide, at error level \( \alpha \), that the data were not generated following a Laplace distribution. Such procedures are explored in detail in Chapter 11.

Tip

The number \( \pi \) can be used in \( R \) with the command \( \text{pi} \).

SECTION 8.2

Matrix operations

Several basic matrix operations are included in the base version of \( R \). Before we introduce them, let \( \lambda \) be a scalar, let \( \mathbf{A} \) and \( \mathbf{B} \) be two real matrices, and let \( \mathbf{C} \) be a complex matrix. We refer the interested reader to [29].

\>
lambda <- 2 # Creating scalar \( \lambda \).
A <- matrix(c(2,3,5,4),nrow=2,ncol=2) # Real matrix.
A
\[
\begin{bmatrix}
1 & 2 \\
3 & 4
\end{bmatrix}
\]
We shall use these objects to illustrate matrix operations.

**8.2.1 Basic matrix operations**

In R, the basic matrix operations are:

- **Adding a scalar: \( \lambda + A \)**
  ```r
  > lambda+A
  [,1] [,2]
  [1,]  4  7
  [2,]  5  6
  ```

- **Addition (entry-wise): \( A + B \)**
  ```r
  > A+B
  [,1] [,2]
  [1,]  3  7
  [2,]  5 11
  ```

- **Subtraction (entrywise): \( A - B \)**
  ```r
  > A-B
  [,1] [,2]
  [1,]  1  3
  [2,]  1 -3
  ```

- **Multiplying by a scalar: \( \lambda A \)**
  ```r
  > lambda*A
  [,1] [,2]
  ```
• Transposition: $A^T$

\[
\begin{bmatrix}
1 & 2 \\
2 & 5 \\
\end{bmatrix}
\]

```
> t(A) [,1] [,2]
 [1,]  2   3
 [2,]  5   4
```

• Conjugation: $\overline{C}$

\[
\begin{bmatrix}
1+0i & 0+1i \\
0-1i & 3+0i \\
\end{bmatrix}
\]

```
> Conj(C) [,1] [,2]
 [1,] 1+0i 0+1i
 [2,] 0-1i 3+0i
```

• Entry-wise multiplication:

\[
\begin{bmatrix}
2 & 10 \\
6 & 28 \\
\end{bmatrix}
\]

```
> A*B [,1] [,2]
 [1,]  2  10
 [2,]  6  28
```

• Dot product: $AB$

\[
\begin{bmatrix}
12 & 39 \\
11 & 34 \\
\end{bmatrix}
\]

```
> A%*%B [,1] [,2]
 [1,] 12 39
 [2,] 11 34
```

• Entry-wise division:

\[
\begin{bmatrix}
2.0 & 2.5 \\
1.5 & 0.5714286 \\
\end{bmatrix}
\]

```
> A/B [,1] [,2]
 [1,] 2.0 2.5000000
 [2,] 1.5 0.5714286
```

• Matrix inversion: $B^{-1}$

\[
\begin{bmatrix}
2.3333333 & -0.6666667 \\
-0.6666667 & 0.3333333 \\
\end{bmatrix}
\]

```
> solve(B) [,1] [,2]
 [1,] 2.3333333 -0.6666667
 [2,] -0.6666667 0.3333333
```

• Matrix division: $A B^{-1}$

\[
\begin{bmatrix}
1.3333333 & 0.3333333 \\
4.3333333 & -0.6666667 \\
\end{bmatrix}
\]

```
> A%*%solve(B) [,1] [,2]
 [1,] 1.333333 0.3333333
 [2,] 4.333333 -0.6666667
```

• Cross product: $A^T B$

\[
\begin{bmatrix}
\end{bmatrix}
\]

```
> crossprod(A,B) # t(A) %*% B
```

Let $M, N, O, P$ be the following matrices:

$$M = \begin{bmatrix} 1 & 2 \\ 3 & 4 \\ 1 & 1 \end{bmatrix}, \quad N = \begin{bmatrix} 3 & 4 \\ 1 & 3 \\ 4 & 1 \end{bmatrix}, \quad O = \begin{bmatrix} 3 & 4 \\ 2 & 1 \\ 3 & 2 \end{bmatrix} \quad \text{and} \quad P = \begin{bmatrix} 3 & 4 \\ 2 & 1 \\ 1 & 2 \end{bmatrix}.$$

Give the dimensions of the matrices $M, N, O$ and $P$. Calculate $M + N$, $M - N$, $3M$, $MO$, $OM$, $M^T$, $P^{-1}$. Check that $PP^{-1} = I_3 = P^{-1}P$.

Let $Q$ and $R$ be the following matrices:

$$Q = \begin{bmatrix} 1 \\ 2 \\ 4 \end{bmatrix} \quad \text{and} \quad R = \begin{bmatrix} 3 & 4 & 1 \end{bmatrix}.$$

Calculate $QR$, $RQ$ and $Q^TPQ$.

### 8.2.2 Outer product

The outer product of column vectors $x$ and $y$ is the matrix $xy^T$ of general element $x_iy_j$.

```r
> x <- seq(1,4)
> y <- seq(4,7)
> outer(x,y,FUN="*")
```

$$\begin{bmatrix} 4 & 5 & 6 & 7 \\ 8 & 10 & 12 & 14 \\ 12 & 15 & 18 & 21 \\ 16 & 20 & 24 & 28 \end{bmatrix}$$

**Tip**

The function `outer()` allows more general operations than simple entry-wise multiplication. For example, the command `outer(x,y,FUN=f)` on vectors $x = (x_1, \ldots, x_n)^T$, $y = (y_1, \ldots, y_n)^T$ with the function $f(x, y)$ produces the following matrix:

$$\begin{pmatrix} f(x_1, y_1) & \cdots & f(x_1, y_n) \\ \vdots & \ddots & \vdots \\ f(x_n, y_1) & \cdots & f(x_n, y_n) \end{pmatrix}$$
8.2 Matrix operations

8.2.3 Kronecker product

If $A$ is an $m \times n$ matrix and $B$ is a $p \times q$ matrix, then the Kronecker product of matrix $A$ by matrix $B$ is the matrix $A \otimes B = \begin{bmatrix} a_{11}B & \cdots & a_{1n}B \\ \vdots & \ddots & \vdots \\ a_{m1}B & \cdots & a_{mn}B \end{bmatrix}$ of dimensions $mp \times nq$.

```r
> kronecker(A, B)
[1,]  2   4   5  10
[2,]  4  14  10  35
[3,]  3   6   4   8
[4,]  6  21   8  28
```

8.2.4 Triangular matrices

It can be useful to get the lower and upper parts of a matrix. This can be done with the functions `lower.tri()` and `upper.tri()`.

```r
> M <- matrix(1:16, nrow=4)
> lower.tri(M)
[1,] FALSE FALSE FALSE FALSE
[2,]  TRUE FALSE FALSE FALSE
[3,]  TRUE  TRUE FALSE FALSE
[4,]  TRUE  TRUE  TRUE FALSE
> upper.tri(M, diag=TRUE)
[1,]  TRUE  TRUE  TRUE  TRUE
[2,] FALSE  TRUE  TRUE  TRUE
[3,] FALSE FALSE  TRUE  TRUE
[4,] FALSE FALSE FALSE  TRUE
> M[lower.tri(M)] <- 0
> M
[1,]  1   5   9  13
[2,]  0   6  10  14
[3,]  0   0  11  15
[4,]  0   0   0  16
```
8.2.5 Operators vec and half vec

The matrix operator vec applied to a matrix $A$ outputs the long column vector \( \text{vec}(A) \) made by concatenating the columns of $A$. It is computed in R with the following instruction:

```r
> vec <- function(M) as.matrix(as.vector(M))
> # or equivalently, but outside a function call:
> # dim(A) <- c(prod(dim(A)),1)
> A
     [,1] [,2]
[1,]  2  5
[2,]  3  4
> vec(A)
     [,1]
[1,]  2
[2,]  3
[3,]  5
[4,]  4
```

The matrix operator vech (for vec half) applied to a matrix $A$ outputs the long column vector \( \text{vech}(A) \) made by concatenating the columns of $A$, but excluding elements above the diagonal of $A$. It is computed in R with the following instruction:

```r
> vech <- function(M) as.matrix(M[lower.tri(M,diag=TRUE)])
> vech(A)
     [,1]
[1,]  2
[2,]  3
[3,]  4
```

8.2.6 Determinant, trace, condition number

The function `det()` computes the determinant of a matrix.

```r
> det(A)
[1] -7
```

There is no R function to compute the trace of a matrix directly, but it is very easy to calculate:

```r
> sum(diag(A))
[1] 6
```

Warning

Do not use the function `trace()` to compute the trace of a matrix. This function is used to debug R code.
8.2 Matrix operations

The condition number is the ratio of the largest and smallest non-zero singular values. A large condition number is an indicator that the matrix has bad numerical properties. It is computed with the function `kappa()`.

```r
> kappa(A, exact=TRUE)
[1] 7.582401
```

8.2.7 Scaling and centring data

The function `scale()` is used to centre and/or scale a matrix. Centring corresponds to subtracting to each column the mean of that column. Scaling corresponds to dividing each column by its standard deviation.

### Centring

```r
> scale(A, scale=FALSE)
[,1] [,2]
[1,] -0.5  0.5
[2,]  0.5 -0.5
attr(,"scaled:center")
[1]  2.5  4.5
```

### Scaling

```r
> scale(A, center=FALSE, scale=sd(A))
[,1]       [,2]
[1,] 2.828427 7.071068
[2,] 4.242641 5.656854
attr(,"scaled:scale")
[1] 0.7071068 0.7071068
```

**Warning**

Note that the function `sd()` calculates a standard deviation with $n - 1$ at the numerator.

To use a scaling factor based on the standard deviation of the population, as is done for example in the French school of data analysis, use the instruction:

```r
> red <- sqrt((nrow(A)-1)/nrow(A))
> scale(A, center=FALSE, scale=sd(A)*red) # t(A/sd(A))/red
[,1]       [,2]
[1,]   4       10
[2,]   6        8
attr(,"scaled:scale")
[1] 0.5 0.5
```

8.2.8 Eigenvalues and eigenvectors

The eigenvalues and eigenvectors of a matrix are returned by the function `eigen()`.
Note that if \( C \) is a Hermitian matrix (i.e. a complex matrix equal to its own conjugate transpose), the function \( \text{eigen} \) can be used to get the eigen-decomposition of \( C \), i.e. \( C = VDV^* \) (where \( V^* \) is the conjugate transpose of \( V \)):

```r
> C <- matrix(c(1,1i,-1i,3),ncol=2)
> e <- eigen(C,symmetric=TRUE)
> V <- e$vectors
> D <- diag(e$values)
> all.equal(C,V%*%D%*%t(Conj(V)))
[1] TRUE
```

8.2.9 Square root of a Hermitian positive-definite matrix

A square root of a positive-definite matrix \( C \) is any matrix \( M \) verifying \( MM^* = C \), where \( M^* \) denotes the conjugate transpose (adjoint matrix) of \( M \). It is usually denoted as \( C^{1/2} \) even when it is not unique. If \( C \) is Hermitian (i.e. a complex matrix equal to its own conjugate transpose or a symmetric real matrix), then \( C^{1/2} \) can be computed as follows:

```r
> e <- eigen(C,symmetric=TRUE)
> V <- e$vectors
> V %*% diag(sqrt(e$values)) %*% t(Conj(V)) # C^{1/2},
# which is
# Hermitian in this case.

[,1]      [,2]
[1,] 0.9238795+0.0000000i 0.000000-0.3826834i
[2,] 0.0000000+0.3826834i 1.689246+0.0000000i
```

The matrix \( C^{-1/2} \) can be computed as follows:

```r
> V %*% diag(1/sqrt(e$values)) %*% t(Conj(V)) # C^{-1/2},
# which is
# Hermitian in this case.

[,1]      [,2]
[1,] 1.194478+0.0000000i 0.000000+0.2705981i
[2,] 0.000000-0.2705981i 0.6532815+0.0000000i
```
8.2 Matrix operations

8.2.10 Singular value decomposition

We wish to write \( C = UDV^* \) where \( D \) denotes the diagonal matrix of the singular values of \( C \) and \( U \) (respectively \( V \)) denotes the matrix of left (respectively right) singular vectors of \( C \). To this end, we use the function \( \text{svd}() \).

```r
> res <- svd(C)
> res
$u
[,1]    [,2]
[1,] -0.3826834+0.0000000i 0.9238795+0.0000000i
[2,] 0.0000000-0.9238795i 0.0000000-0.3826834i
$v
[,1]    [,2]
[1,] -0.3826834+0.0000000i 0.9238795+0.0000000i
[2,] 0.0000000-0.9238795i 0.0000000-0.3826834i
> D <- diag(res$d)
> U <- res$u
> V <- res$v
> all.equal(C,U%*%D%*%t(Conj(V))) # A = UDV^*
[1] TRUE
```

Tip

To compute the Moore-Penrose pseudo-inverse of a (non invertible) matrix, use the following function:

```r
> mpinv <- function(M,eps=1e-13) {
+ s <- svd(M)
+ e <- s$d
+ e[e>eps] <- 1/e[e>eps]
+ return(s$v%*%diag(e)%*%t(s$u))
+ }
```

8.2.11 Cholesky decomposition

Let \( B \) be a symmetric and positive-definite real matrix. We wish to write \( B = U^T U = LL^T \), where \( U \) (respectively \( L \)) is an upper (respectively lower) triangular matrix. Note that this implies that \( U \) is a square root of \( B \). To get this decomposition, use the function \( \text{chol}() \).

```r
> U <- chol(B) # This is another method for calculating # B^{1/2}.
> L <- t(U)
> U
```
8 Basic Mathematics: matrix operations, integration, optimization

\[
\begin{bmatrix}
1 & 2 \\
2 & 1
\end{bmatrix}
\]

\[
> \text{all.equal}(B, t(U) %*% U) \quad \# \; B = U^T U
\]

\[\text{TRUE}\]

Note that the function `chol2inv()` can be used to compute the inverse \(B^{-1}\) of a square symmetric and positive definite matrix \(B\), using its Cholesky decomposition.

\[
> B
\]

\[
\begin{bmatrix}
1 & 2 \\
2 & 7
\end{bmatrix}
\]

\[
> \text{chol2inv}(U) \quad \# \; \text{This is } B^{-1}.
\]

\[
\begin{bmatrix}
2.3333333 & -0.6666667 \\
-0.6666667 & 0.3333333
\end{bmatrix}
\]

\[
> \text{all.equal(chol2inv(U), solve(B))}
\]

\[\text{TRUE}\]

Finally, note that the function `chol()` can be used to compute \(B^{-1/2}\) as follows:

\[
> \text{solve(chol(B))}\quad \# \; \text{This is a version of } B^{-1/2}.
\]

\[
\begin{bmatrix}
1 & -1.1547005 \\
0 & 0.5773503
\end{bmatrix}
\]

### 8.2.12 QR decomposition

We wish to write \(A = QR\), where \(Q\) is an orthogonal matrix \((QQ^T = Q^T Q = I)\) and \(R\) is an upper triangular matrix.

\[
> \text{res <- qr(A)}
\]

\[
> Q <- \text{qr.Q(res)}
\]

\[
\begin{bmatrix}
-0.5547002 & -0.8320503 \\
-0.8320503 & 0.5547002
\end{bmatrix}
\]

\[
> \text{all.equal(I2, Q%*%t(Q))} \quad \# \; I_2 = QQ^T
\]

\[\text{TRUE}\]

\[
> R <- \text{qr.R(res)}
\]

\[
\begin{bmatrix}
-3.605551 & -6.101702 \\
0.000000 & -1.941451
\end{bmatrix}
\]

\[
> \text{all.equal(A, Q %*% R)} \quad \# \; A = QR
\]

\[\text{TRUE}\]
8.3 Numerical integration

The numerical value of an integral can be computed in R with the function `integrate()`.

A few examples will help illustrate this function. Suppose you wish to check numerically that
\[ \int_{-\infty}^{\infty} \frac{\exp(-x^2/2)}{\sqrt{2\pi}} \, dx = 1. \]
Use the following procedure:

```r
> myf <- function(x) {exp(-x^2/2)/sqrt(2*pi)}
> integrate(myf, lower=-Inf, upper=Inf)$value
[1] 1
```

Note that it is also possible to integrate functions of several variables. Thus, suppose you wish to check numerically that
\[ \int_{x=0}^{1} \int_{y=2}^{3} \cos(x+y) \, dy \, dx = 2 \cos(3) - \cos(4) - \cos(2). \]
Use the following procedure:

```r
> myf <- function(x) {
+   res <- vector("integer", length(x))
+   for (i in 1:length(x)) {
+     res[i] <- integrate(f=function(y,x){cos(x+y)}, lower=2, upper=3, x=x[i])$value
+   }
+   return(res)
+ }
> integrate(myf, lower=0, upper=1)$value
[1] -0.9101945
> 2*cos(3)-cos(4)-cos(2)
[1] -0.9101945
```

Note that the function `integrate()` also returns the precision of the numerical calculation.
Check numerically that the function \( f_X(x) = \frac{1}{2} \left( 1 + \frac{|x-1|}{2} \right)^{-3} \) \( \mathbb{I}_{[1,\infty]}(x) \) is a probability distribution function, i.e., that it integrates to 1. It is in fact the density function of a generalized Pareto distribution with parameters (1,2,1/4).

### 8.4.1 Symbolic differentiation

\( \text{R} \) has very limited capabilities for symbolic calculus and we shall not dwell on this aspect. Note however that \( \text{R} \) includes symbolic differentiation functions: `D()` and `deriv()`. For instance:

```r
> D(expression(sin(cos(x + y^2))), "x")  # Differentiate with respect to x.
-(cos(cos(x + y^2)) * sin(x + y^2))
> D(expression(sin(cos(x + y^2))), "y")  # Differentiate with respect to y.
-(cos(cos(x + y^2)) * (sin(x + y^2) * (2 * y)))
> f <- deriv("x^2", "x", function(x))  # Differentiate \# \# x^2 \# and get \# 2x.
> f(3)  # Returns 3^2 and 2*3
[1] 9
attr("gradient")
   x
[1,] 6
```

The package Ryacas interfaces \( \text{R} \) with the formal calculus software Yacas, available online at http://yacas.sourceforge.net. Install and load the package Ryacas, then try the command `vignette("Ryacas")`. 
8.4.2 Numerical differentiation

Numerical differentiation can be done in R with the function `grad()` from the package `numDeriv`.

```r
> require(numDeriv)
> f <- function(x) x^2  # Function of one variable.
> grad(f,c(2,1,3,5))  # Computes the derivative at several (scalar) points.
[1] 4 2 6 10
```

This package also includes the functions `hessian()` to compute second-order derivatives, but only at a single (vectorial) point.

```r
> g <- function(x) x[1]*x[2]^2  # Function of two variables.
> grad(g,c(2,1))  # Calculates the derivative at a single (vectorial) point.
[1] 1 4
> hessian(g,c(2,1))  # Calculates the second-order derivative at a single (vectorial) point.
[,1] [,2]
[1,] 4.210428e-14 2
[2,] 2.000000e+00 4
```

The function `numericDeriv()`, which is trickier to use, returns the gradient of a function of several variables at several vectorial points. For instance, the following instructions compute the gradient vector of the function $xy^2$ at (2, 1) and (3, 4). The results are (1, 4) and (16, 24).

```r
> h <- function(x,y) x*y^2  # Function of two variables.
> x <- c(2,3)
> y <- c(1,4)
> attributes(numericDeriv(quote(h(x,y)),c("x","y")))$gradient
[,1] [,2] [1,] 1 0 4 0 [2,] 0 16 0 24
```

## 8.5 Optimization

### 8.5.1 Optimization functions

Optimizing a function means finding where it reaches its maximum or its minimum. There are several R functions to this end, based on various algorithms: `optimize()`, `optim()`, `nlm()`, `constrOptim()`, `nlminb()`.
• **One-dimensional optimization**

The function `optimize()`, which only works in one dimension, is the easiest to manipulate. As an example, suppose you wish to find the value and argument of the minimum of the function $\cos(x^2)$ over the interval $[0, 2]$. This function is plotted on the next figure.

The function `optimize()` solves this problem numerically.

```r
> optimize(f=function(x) {cos(x^2)}, lower=0, upper=2)
$minimum
[1] 1.772453
$objective
[1] -1
```

The minimum is $-1$ and is reached at $x = 1.772453$.

**Tip**

The argument `maximum=TRUE` of the function `optimize()` is used to compute the maximum rather than the minimum of a function.

• **Multidimensional optimization**

We wish to find the maximum of the function of two variables $f(x, y) = 10 \sin(\sqrt{(x-3)^2+(y-4)^2}) \alpha/2$ with $\alpha = 1.1$. We use the function `nlm()`, which calculates the minimum of a function. The function $f$ is plotted on Figure 8.1 using the following R instructions:
Finding the maximum of $f$ is equivalent to finding the minimum of $-f$, so we use `nlm()` on the function $-f$.

```r
def <- function(z, alpha=1.1) {
  x <- z[1]
  y <- z[2]
  r <- sqrt((x-3)^2+(y-4)^2)
  - 10 * sin(r)/r^alpha
}
def <- function(z, alpha=1.1) {
  x <- z[1]
  y <- z[2]
  r <- sqrt((x-3)^2+(y-4)^2)
  - 10 * sin(r)/r^alpha
}
res <- nlm(f,c(0,0)) # The second effective argument gives # the initial values.
res
$minimum
[1] -1.046464
$estimate
[1] -1.627385 -2.169848
$gradient
[1] -1.534979e-07 1.139977e-07
$code
[1] 1
$iterations
[1] 7
```
The maximum is \((-1) \times \text{res$\\text{minimum}$} = 1.046464\) and is reached at \(\text{res$\\text{estimate}$} = (-1.627, -2.169)\).

In `nlm()`, you can specify the value of a parameter of the function to minimize. Thus, to maximize \(f\) with \(\alpha = 2\), use the following instruction: `nlm(f, c(0, 0), alpha=2)`

- **Constrained optimization**

For optimization subject to simple constraints, such as \(-c \leq x \leq b\) and \(-c \leq y \leq d\), use the function `nlminb()` and its arguments `lower` and `upper`. For example, suppose we wish to find the three maxima of the surface of equation \(e^{-(x-1.2)^2 - (y-2)^2} \cos(2\pi(x - 1.2))\) over the range \([-1, 3] \times [0, 4]\), whose plot is obtained using the following instructions:

```r
> f <- function(x, y) exp(-(x-1.2)^2-(y-2)^2)*cos((x-1.2)*pi*2)
> x <- seq(-1,3,0.1)
> y <- seq(0,4,0.1)
> persp(x,y,outer(x,y,f),theta=30,phi=30,expand=0.5,
> + col="lightblue",ticktype="detailed")
```

First, we search for the global maximum. Visual inspection shows that it is reached in the range \([0.5, 1.5] \times [0, 4]\).

```r
> f <- function(x) -exp(-(x[1]-1.2)^2-(x[2]-2)^2)*
+ cos(2*pi*(x[1]-1.2))
> nlminb(c(0.8,0),f,lower=c(0.5,0),upper=c(1.5,4))
$par
[1] 1.200000 2.000000
```
The (global) maximum is \((-1) \times \text{res$objective}=1\) and is reached at \(\text{res$par}=(1.2, 2)\).

We conclude with a search over the ranges \([-1, 0.5] \times [0, 4]\) and \([1.5, 3] \times [0, 4]\), with the following instructions:

```r
nlminb(c(0, 0), f, lower=c(-1, 0), upper=c(0.5, 4))
nlminb(c(2, 0), f, lower=c(1.5, 0), upper=c(3, 4))
```

Note

For linear constraints such as

\[
\begin{pmatrix}
a & b \\
c & d
\end{pmatrix}
\begin{pmatrix}
x \\
y
\end{pmatrix}
- \begin{pmatrix}
c_1 \\
c_2
\end{pmatrix} \geq 0 \iff \begin{cases}
a x + b y - c_1 \geq 0 \\
c x + d y - c_2 \geq 0
\end{cases}
\]

you can use the function `constrOptim()` with arguments `ui=\(\begin{pmatrix}a & b \\
c & d\end{pmatrix}\)` and `ci=\(\begin{pmatrix}c_1 \\
c_2\end{pmatrix}\)`.

### 8.5.2 Roots of a function

The roots (or zeros) of a function \(f\) are defined as the solutions to the equation \(f(x) = 0\).

- **Single root**
  If there is a single root, use the function `uniroot()` which performs a one-dimension search over a given interval. For example, here is how you would find the value at which the function \(\cos(x^2)\) vanishes, over the interval \([0, 2]\) (we mentioned this function when we introduced one-dimension optimization). The analytical solution to this simple problem is \(x = \sqrt{\pi/2} = 1.253314\).
- **Roots of a polynomial**
  
  The function `polyroot()` finds all (possibly complex) roots of a polynomial. For example, this instructions finds the roots of the polynomial $P(x) = 3 - 8x + x^2$.

  ```r
  > polyroot(c(3,-8,1))
  [1] 0.3944487+0i 7.6055513+0i
  ```

  ```r
  > uniroot(f=function(x){cos(x^2)},lower=0,upper=2, +
  + tol=0.00001)$root
  [1] 1.253314
  ```
8.5 Optimization

Memorandum

*round()*: round numbers
*abs()*: absolute value
*sqrt()*: square root
*exp(), log()*: exponential, logarithm
*max(), min()*: maximum, minimum
*sum(), prod()*: sum, product
*cummax(), cummin(), cumprod(), cumsum()*: cumulative maxima, minima, products and sums
*cos(), sin()*: cosine, sine
*%*%*: matrix multiplication operator
*t(), solve()*: matrix transposition, inversion
*outer(), kronecker()*: external product, Kronecker product

*eigen()*: eigenvalues and eigenvectors of a matrix
*svd(), chol(), qr()*: matrix decompositions (singular values, Cholesky, QR)
*integrate()*: numerical integration
*D(), deriv()*: symbolic differentiation
*grad(), hessian()*: numerical differentiation with package numDeriv
*optimize(), nlm(), nlminb()*: function optimization
*uniroot(), polyroot()*: roots of a function

Exercises

8.1- Which function calculates binomial coefficients?
8.2- Give the instruction to compute the sum of the first \( n \) integers.
8.3- Which function returns the range of a sample?
8.4- What is the output of this instruction:
\[
\text{matrix(c(1,0,0,1),nrow=2)} \ast \text{matrix(1:4,nrow=2)}
\]
8.5- What is the symbol for matrix multiplication?
8.6- Which function transposes a matrix? Which function inverses a matrix?
8.7- Give the instruction to create the identity matrix of size 5.
8.8- Give the instructions to calculate the determinant and the trace of a matrix.
8.9- Give the instruction to centre and scale a matrix \( A \).
8.10- Which function calculates the eigenvalues and eigenvectors of a matrix?
8.11- Give the instruction to integrate numerically the function \( 3x^2 + 2 \) over \([-1, 1]\).
8.12- Give the instruction to find the maximum of the function \( \sin^2(x) \) over \([0, 2]\).
8.13- Which function would you use to find where a function vanishes? Where a polynomial vanishes?
Worksheet

Matrix operations, optimization, integration

A- A first optimization problem

The aim of this practical is to find the eigenvalues of the following matrix, using several methods.

> A

\[
\begin{bmatrix}
1 & 2 \\
3 & 4
\end{bmatrix}
\]

8.1- Create a function called \texttt{myf()} which evaluates the characteristic polynomial \( P(x) = \det(A - xI_2) \) at point \( x \) (hint: use the function \texttt{det()}). Recall that the eigenvalues of a matrix are the roots of its characteristic polynomial.

8.2- Change the function \texttt{myf()} so that it takes vector values.

8.3- Plot the function \texttt{myf()} over the range \([-10, 10]\). Add axes.

8.4- Use the function \texttt{uniroot()} twice to find the two roots of this function.

8.5- Find the coefficients of the polynomial \( P(x) \), then use the function \texttt{polyroot()} to calculate the roots of this polynomial.

8.6- Check your results with the function \texttt{eigen()}.

B- A second optimization problem

The following information is given about the figure below:

- \((MH)\) is the perpendicular bisector of \([DC]\)
- \(Q\) is the orthogonal projection of \(M\) onto \((BC)\)
- \(g(\alpha) = MA + MB + MH\) with \(\alpha = \angle MB \in [0; \pi/2]\)
- \(AB = 10\) and \(BC = 6\)
8.5 Optimization

The aim of this practical is to find the angle $\alpha$ which minimizes $g(\alpha)$.

Recall the following trigonometric identities:

- \[ \cos(\theta) = \frac{\text{length of adjacent side}}{\text{length of hypotenuse}}; \]
- \[ \sin(\theta) = \frac{\text{length of opposite side}}{\text{length of hypotenuse}}; \]
- \[ \tan(\theta) = \frac{\text{length of opposite side}}{\text{length of adjacent side}} = \frac{\sin(\theta)}{\cos(\theta)}; \]
- \[ \sin(\pi/2 - \theta) = \cos(\theta). \]

8.1- Reproduce the figure with R.
8.2- Show analytically that $g(\alpha) = 5(2 - \sin(\alpha))/(\cos(\alpha)) + 6$.
8.3- In R, create the function g.
8.4- Calculate numerically the value and argument of the minimum of $g(\alpha)$.
8.5- Calculate analytically $g'(\alpha)$.
8.6- Check your result with symbolic differentiation.
8.7- In R, create this function, which you can call gprime.
8.8- Calculate numerically the root of $g'(\alpha)$. Check that you get the same result as before.
C- Standard normal table

We shall use the function \texttt{integrate()} to create a table for the distribution \(N(0, 1)\).

Let \( \Phi(x) = \int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}} e^{-\frac{t^2}{2}} dt \) be the cumulative density function of \(N(0, 1)\). It is well known that \( \Phi(-x) = 1 - \Phi(x) \). We shall thus only create the table for positive values of \(x\).

8.1- Create a function \texttt{phi()} which takes as input a vector \(x\) of length \(n\) and returns the vector of values \( \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2}}, i = 1, \ldots, n \).

8.2- Use the function \texttt{integrate()} to compute \( \Phi(x) \) for all \(x\) in the following vector: \texttt{quantiles <- seq(0,5.5,by=0.1)}. Store these values in a vector called \texttt{probs}.

8.3- Use the function \texttt{all.equal()} to compare these results with those given by the function \texttt{pnorm()}.

8.4- Plot the values of \( \Phi(x) \) for all \(x\) and all \(-x\) in \texttt{quantiles} (hint: use the function \texttt{rev()}).

8.5- Plot the function \texttt{pnorm()} in blue over the previous curve. Check that the two plots coincide perfectly.

D- Principal components analysis

Principal components analysis is used to describe the proximity of individuals on which several quantitative traits have been measured. This method requires many matrix operations, and is thus a good way to put into practice the notions introduced at the beginning of this chapter.

Data were collected in the wine region of Bordeaux. They include:

- four weather traits:
  - TEMPER: sum of daily average temperatures (in degrees Celsius),
  - SUN: length of insolation (in hours),
  - HEAT: number of days of strong heat,
  - RAIN: rainfall (in mm);
- wine quality (QUALITY), as determined by wine-tasters:
  1 = good wine, 2 = average wine, 3 = mediocre wine.

We shall represent these quantitative data on a scatter plot after projecting the data onto a subspace (a plane) chosen so as to limit the loss of information caused by the projection.

8.1- Import into the variable \texttt{climatewine} the contents of the data file \url{http://www.biostatisticien.eu/springeR/climatewine.csv}

8.2- Store in matrix \texttt{X} the variables \texttt{TEMPER, SUN, HEAT, RAIN} (hint: \texttt{as.matrix()}).
8.3- Calculate the centre (of gravity) \( \mathbf{g} \) of the scatter plot of individuals included in \( \mathbf{X} \) (vector of column averages) with the function `colMeans()`. Display it with two decimal places.

8.4- Use the function `scale()` to calculate the matrix \( \mathbf{X} = (x_{ij}) \) of centred data, and store it in the variable `Xdot`.

8.5- Calculate the global inertia of the scatter plot, which represents the dispersion of the points:

\[
I = \frac{1}{n} \sum_{i=1}^{n} \sum_{j=1}^{p} x_{ij}^2,
\]

where \( n \) is the number of individuals in \( \mathbf{X} \).

8.6- The contribution of individual \( i \) to the global inertia is given by the formula

\[
\frac{1}{n} \sum_{j=1}^{p} x_{ij}^2,
\]

where \( p \) is the number of variables (four in this case).

8.7- Create the column matrix \( \mathbf{onen} \) of length \( n \), containing only 1’s.

8.8- Check that the centre of gravity \( \mathbf{g} \) of the scatter plot is also given by the formula

\[
\mathbf{g} = \frac{1}{n} \mathbf{X}^T \mathbf{1}_n.
\]

8.9- Check that the matrix \( \mathbf{Xdot} \) of centred data is also given by the formula

\[
\mathbf{Xdot} = \mathbf{X} - \frac{1}{n} \mathbf{g}^T.
\]

8.10- Calculate the matrix of covariances \( \mathbf{S} \) with the formula

\[
\mathbf{S} = \frac{1}{n} \mathbf{X}^T \mathbf{X}.
\]

Try to reproduce this result with the function `cov()`.

8.11- Use the matrix \( \mathbf{S} \) to calculate the diagonal matrix \( \mathbf{Doneovers} \) containing the inverses of standard deviations:

\[
\mathbf{Doneovers} = \text{diag}(1/s_1, \ldots, 1/s_p).
\]

8.12- Calculate the matrix \( \mathbf{Z} \) of scaled and centred data with the formula

\[
\mathbf{Z} = \mathbf{X} \mathbf{Doneovers}.
\]

8.13- Calculate the matrix of correlations \( \mathbf{R} \) with the formula

\[
\mathbf{R} = \frac{1}{n} \mathbf{Z}^T \mathbf{Z}.
\]

Try to reproduce this result with the function `cor()`.

8.14- Calculate the diagonal matrix \( \Lambda \) of eigenvalues (\( \Lambda \)) and the matrix \( \mathbf{W} \) of eigenvectors (\( \mathbf{W} \)) of the correlation matrix \( \mathbf{R} \). The matrix \( \mathbf{W} \) contains the coordinates of a new basis in which we shall represent the individuals.

8.15- Plot the circle of correlations, which is a circle of radius 1, over which you should overlay arrows starting at the origin and ending at the points with coordinates given by the first two columns of the matrix \( \mathbf{W} \Lambda^{1/2} \). On the same plot, add the names of the variables at the end of the four arrows.

8.16- The total inertia of the scaled and centred scatter plot is equal to the number of variables (four in this case). It can be decomposed into a sum of inertias contributed by each one of the four axes of the basis of \( \mathbf{W} \), which are given by the diagonal of \( \Lambda \). Calculate the vector of percentages of total inertia explained by the first \( k \) axes (\( 1 \leq k \leq p \)). What percentage of the inertia is explained by the first two axes?

8.17- Calculate the matrix \( \mathbf{C_W} \) of principal components with the formula

\[
\mathbf{C_W} = \mathbf{Z} \mathbf{W}.
\]

The principal components are the coordinates of the individuals in the new basis described by \( \mathbf{W} \).

8.18- Open a new graphics window and plot the individuals projected onto the first principal plane, i.e. with coordinates given by the first two columns of \( \mathbf{C_W} \). Add the names of the individuals onto the plot.
8.19- Draw the last plot again, but this time plot in red (respectively blue, green) good wines (respectively average wines, mediocre wines). Add a caption.

8.20- The quality of representation of individual \( i \) on the first principal plane is given by the formula \( \sum_{p=1}^{\text{rows}} c_{ij}^2 \), where \( c_{ij} \) is the entry at row \( i \) and column \( j \) of the matrix \( C_W \). Calculate the vector \( QLT \) of qualities of representation of individuals on the first principal plane. Display \( QLT \) with two decimal places.

8.21- We shall briefly explore package ade4 which performs PCA. Install and load this package.

8.22- Type the following instructions:

```r
rownames(X) <- climatewine[,1]
res <- dudi.pca(X) # Answer 2 to the question you are asked.
scatter(res)
s.class(res$li,as.factor(climatewine[,6]))
```
Chapter 9
Descriptive statistics

Goals
This chapter describes the procedures in R to structure your variables, draw standard summary plots of your data and calculate simple numerical statistical summaries on a data set. The data used to illustrate this chapter are from the dataset NUTRIELDERLY. We also give a few examples of functions to produce prettier plots, useful for presentations or reports.

SECTION 9.1
Introduction

All examples in this chapter are based on the data file nutrition_elderly.xls which you can import into R using one of the methods described in Chapter 2. For example, you could use the following instructions (remember to install the file http://www.biostatisticien.eu/springeR/Rtools29.exe if you are working under Microsoft Windows):

> require(gdata) # Gives access to the function read.xls()
> nutrielderly <- read.xls(
+ "http://www.biostatisticien.eu/springeR/nutrition_elderly.xls")
This table includes measures of thirteen variables for 226 individuals.

In the remainder of the chapter, we shall assume that the data used for the various examples have been structured as explained in the next section.

SECTION 9.2

Structuring variables according to type

The thirteen variables from the dataset NutriElderly can be sorted by type with the algorithm given in the next figure. Recall that the type of a variable $X$ is determined by the set $E_X$ of observable modalities, and not by the modalities which are actually observed.
9.2 Structuring variables according to type

![Algorithm to determine the type of a variable.](image)

- **Order relation on \( E_X \)?**
  - **NO**
  - Qualitative
  - **YES**
    - Is \( E_X \) an union of intervals? (of positive length)
      - **NO**
      - Ordinal
      - **YES**
        - Can we interpret the differences between any two terms of \( E_X \)?
          - **NO**
          - Continuous quantitative
          - **YES**
            - Discrete quantitative

With this algorithm, we get the following summary table:

<table>
<thead>
<tr>
<th>Qualitative variables</th>
<th>gender, situation, and fat</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ordinal variables</td>
<td>meat, fish, raw_fruit, cooked_fruit, veg and chocol</td>
</tr>
<tr>
<td>Discrete quantitative variables</td>
<td>tea and coffee</td>
</tr>
<tr>
<td>Continuous quantitative variables</td>
<td>weight, weight and age</td>
</tr>
</tbody>
</table>

First of all, we shall set up an adapted \( R \) structure for each variable.

### 9.2.1 Structuring qualitative variables

For qualitative variables, set up the structure with the function `as.factor()`. It might be useful to also use the function `levels()` to recode the modalities of a
Let us perform these operations on the qualitative variables from our dataset:

```r
> gender <- as.factor(gender)
> levels(gender) <- c("Male","Female")
> situation <- as.factor(situation)
> levels(situation) <- c("single","couple","family","other")
> fat <- as.factor(fat)
> levels(fat) <- c("butter","margarine","peanut",
+ "sunflower","olive","Isio4","rapeseed","duck")
```

Note that if the variable is coded as presence/absence, you can also use an R structure with a vector of logical values:

```r
> smoker <- c(1,0,0,1,0,1,0,1,0,0) # 10 smokers(=1)/non-smokers(=0).
> smoker
[1] 1 0 0 1 0 1 0 1 0 0
> smoker <- as.logical(smoker)
> smoker
[1] TRUE FALSE FALSE TRUE FALSE TRUE FALSE TRUE FALSE
```

If you also wish to associate a name to your modalities, you can proceed as follows:

```r
> smoker <- c(smokes=smoker)
> smoker
smokes1 smokes2 smokes3 smokes4 smokes5 smokes6 smokes7
  TRUE FALSE FALSE TRUE FALSE TRUE FALSE
smokes8 smokes9 smokes10
  TRUE FALSE FALSE
```

However, we advise against coding presence/absence variables as logical values, as this hinders their use in other R functions, especially for graphical representation.

For advanced users:

If you start with a variable which is already structured into factors, for example:

```r
> smoker <- as.factor(c("Smoker","NonSmoker","NonSmoker",
+ "Smoker","NonSmoker","Smoker","NonSmoker",
+ "Smoker","NonSmoker","NonSmoker"))
> smoker
[1] Smoker  NonSmoker NonSmoker Smoker  NonSmoker
[6] Smoker  NonSmoker Smoker  NonSmoker
Levels: NonSmoker Smoker
```

you can code it as logical values with the following procedure:
9.2 Structuring variables according to type

9.2.2 Structuring ordinal variables

For ordinal variables, the structure can be set up with the function `as.ordered()`. It can also be useful to recode the modalities of an ordinal variable with the function `levels()`.

Let us perform these operations on the ordinal variables from our dataset:

```r
> meat <- as.ordered(meat)
> fish <- as.ordered(fish)
> raw_fruit <- as.ordered(raw_fruit)
> cooked_fruit_veg <- as.ordered(cooked_fruit_veg)
> chocol <- as.ordered(chocol)
> mylevels <- c("never","< 1/week.","1/week.","2-3/week.",
+ "4-6/week.","1/day")
> levels(chocol) <- levels(cooked_fruit_veg) <-
+ levels(raw_fruit) <- mylevels
> levels(fish) <- levels(meat) <- mylevels
```

9.2.3 Structuring discrete quantitative data

For a discrete variable, the structure is set up with the function `as.integer()`.

```r
> tea <- as.integer(tea)
> coffee <- as.integer(coffee)
```

This only works if the data take integer values.

9.2.4 Structuring continuous quantitative variables

For a continuous variable, the structure is set up with the function `as.double()`.

```r
> height <- as.double(height)
> weight <- as.double(weight)
> age <- as.double(age)
```
For a given dataset, which plots and numerical summaries can be performed depends strongly on the structure of the data table, and on the type of the variable(s) in play. In this chapter, we detail how data can be organized into tables in R.

### 9.3.1 Individual data tables

This is the most common organization type. The data consist of measures of one or several variables for each of \( N \) individuals in a population. Refer to Chapter 2 to find out how to import data into R. These data are usually organized in a data.frame.

### 9.3.2 Tables of counts and frequency tables

It is often interesting to represent a table of individual data (or raw data table) in a more condensed form. A table of counts or a table of frequencies makes it easier to understand the distribution of a variable, especially if the data are qualitative or ordinal. Such tables are obtained with the function `table()`.

```r
> tc <- table(fat)  # Table of counts.
> tc

fat
butter margarine peanut sunflower olive Isio4
15 27 48 68 40 23
rapeseed duck
1 4
> tf <- tc/length(fat)  # Frequency table.
> tf

fat
butter margarine peanut sunflower olive Isio4
0.06637168 0.11946903 0.21238938 0.30088496 0.17699115
rapeseed duck
0.10176991 0.00442478
> levels(fat)  # Levels.
[1] "butter" "margarine" "peanut" "sunflower" "olive" "Isio4" "rapeseed" "duck"
> nlevels(fat)  # Number of levels.
[1] 8
```
9.3.3 Tables of grouped data

It is sometimes interesting to represent a table of individual data (or raw data table), of one or several quantitative variables, in a more condensed form. To this end, use a table of grouped data, giving the count (or frequency) of predefined classes.

Note that you can use the function `hist()` and specify the boundaries of classes in the argument `breaks`; it will then return the count in each of these classes. The default value of the argument `breaks` is "Sturges", which automatically calculates the classes.

```r
> res <- hist(height, plot=FALSE)
> nn <- as.character(res$breaks)
> x <- as.table(res$counts)
> dimnames(x) <- list(paste(nn[-length(nn)], nn[-1], sep="-"))
> x

9.3.4 Cross tabulation

9.3.4.1 Contingency tables

When given a table of individual data, you can use the function `table()` to get the observed contingency table for a couple (X, Y).

```r
> mytable <- table(gender, situation)
> mytable

<table>
<thead>
<tr>
<th></th>
<th>single</th>
<th>couple</th>
<th>family</th>
<th>other</th>
</tr>
</thead>
<tbody>
<tr>
<td>Male</td>
<td>20</td>
<td>63</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Female</td>
<td>78</td>
<td>56</td>
<td>7</td>
<td>0</td>
</tr>
</tbody>
</table>

To add margins to this table, use the function `addmargins()`.

```r
> table.complete <- addmargins(mytable, FUN=sum, quiet=TRUE)
> table.complete

<table>
<thead>
<tr>
<th></th>
<th>single</th>
<th>couple</th>
<th>family</th>
<th>other</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Male</td>
<td>20</td>
<td>63</td>
<td>2</td>
<td>0</td>
<td>85</td>
</tr>
<tr>
<td>Female</td>
<td>78</td>
<td>56</td>
<td>7</td>
<td>0</td>
<td>141</td>
</tr>
<tr>
<td>sum</td>
<td>98</td>
<td>119</td>
<td>9</td>
<td>0</td>
<td>226</td>
</tr>
</tbody>
</table>
```
9.3.4.2 Joint distribution

The joint distribution table (or table of relative frequencies) for a couple \((X, Y)\) is obtained from the contingency table `mytable`.

```r
freqtable <- mytable/sum(mytable)
> freqtable
situation gender single couple family other
Male  0.088495575 0.278761062 0.008849558 0.000000000
Female 0.345132743 0.247787611 0.030973451 0.000000000

To get margins, use one of the following instructions:

```r
> Total <- sum
> addmargins(freqtable,FUN=Total,quiet=TRUE)

```r
situation gender single couple family other
Male  0.088495575 0.278761062 0.008849558 0.000000000
Female 0.345132743 0.247787611 0.030973451 0.000000000
Total  0.433628319 0.526548673 0.039823009 0.000000000

situation gender sum
Male 0.376106195
Female 0.623893805
Total 1.000000000
```

```r
freqtabletotal <- table.complete/table.complete[length(table.complete)]
> freqtabletotal
situation gender single couple family other
Male  0.088495575 0.278761062 0.008849558 0.000000000
Female 0.345132743 0.247787611 0.030973451 0.000000000
sum  0.433628319 0.526548673 0.039823009 0.000000000

situation gender sum
Male 0.376106195
Female 0.623893805
sum 1.000000000
```
9.3.4.3 Marginal distributions

The marginals of a distribution or contingency table freqtable are obtained with the function margin.table().

```r
> margin.table(freqtable, 1) # Right margin.
gender
   Male Female
0.3761062 0.6238938
> margin.table(freqtable, 2) # Bottom margin.
situation
   single couple family other
0.43362832 0.52654867 0.03982301 0.00000000
```

Warning
When the distribution (or contingency) table is complete, i.e. when it already includes the marginals (as is the case for freqtabletotal), do not extract them with the function margin.table(), but proceed thus:

```r
> freqtabletotal[, ncol(freqtabletotal)] # Right margin.
   Male Female sum
0.3761062 0.6238938 1.0000000
> freqtabletotal[nrow(freqtabletotal),] # Bottom margin.
   single couple family other sum
0.43362832 0.52654867 0.03982301 0.00000000 1.00000000
```

9.3.4.4 Conditional distributions

Conditional distribution tables are obtained with the function prop.table().

- Conditional distribution of situation knowing the values of gender:

```r
> prop.table(mytable, 1)
situation
gender single couple family other
   Male 0.23529412 0.74117647 0.02352941 0.00000000
   Female 0.55319149 0.39716312 0.04964539 0.00000000
> addmargins(prop.table(mytable, 1), margin=2, FUN=sum) # Add Total.
situation
gender single couple family other sum
   Male 0.23529412 0.74117647 0.02352941 0.00000000 1.00000000
   Female 0.55319149 0.39716312 0.04964539 0.00000000 1.00000000
```

- Conditional distribution of gender knowing situation:

```r
> prop.table(mytable, 2)
situation
gender single couple family other
   Male 0.23529412 0.74117647 0.02352941 0.00000000
   Female 0.55319149 0.39716312 0.04964539 0.00000000
> addmargins(prop.table(mytable, 2), margin=2, FUN=sum) # Add Total.
situation
gender single couple family other sum
    Male 1.00000000
    Female 1.00000000
```
> prop.table(mytable, 2)
  situation
gender single couple family other
Male  0.2040816 0.5294118 0.2222222
Female 0.7959184 0.4705882 0.7777778

> addmargins(prop.table(mytable, 2), margin=1, FUN=sum)  # Add Total.
  situation
gender single couple family other
Male  0.2040816 0.5294118 0.2222222
Female 0.7959184 0.4705882 0.7777778
sum 1.0000000 1.0000000 1.0000000

SECTION 9.4

Numerical summaries

For simplicity, we present all numerical summaries on the vector \( \mathbf{x} = (x_1, \ldots, x_N)^T \). This vector is the set of \( N \) values of the variable \( X \) measured on a population of size \( N \) (standard situation in descriptive statistics). When the vector \( x \) represents a subsample, we shall denote its length by \( n \). Examples are mainly based on the data vector height.

Warning
Numerical summaries cannot be computed when some data are missing (NA). If necessary, missing data can be omitted with the function `na.omit()`.

> x <- na.omit(height)  # Useless in this case since height has no NA.

9.4.1 Summaries of the location of a distribution

9.4.1.1 Modes

The modes of variable \( X \) are the values that occur most frequently. They can be computed for a variable of any type, although for continuous quantitative variables, the modal class should be used instead. Note that the mode may be unique, in which case the distribution is said to be unimodal, as opposed to multimodal.

> tabtea <- table(tea)
> names(which.max(tabtea))  # Getting a unique mode.
[1] "0"
In this case, the variable tea (number of cups of tea per day) is unimodal.

**Tip**

For a quantitative variable, you can use the function `as.numeric()` on the above results to get numerical values.

### 9.4.1.2 Median

The median of a statistical series is the value $m_e$ which splits the series into two halves (larger and smaller than $m_e$) of same size, when the values are sorted from smallest to largest. It is a location criterion, which is obviously relevant only for purely qualitative variables. To compute it, there are two cases:

- if the total sample size $N$ of the series is odd, then the median is the value at position $\frac{N+1}{2}$;
- if the total sample size $N$ is even, then any value between the values at positions $\frac{N}{2}$ and $\frac{N}{2} + 1$ can be used as a median of the series. In practice, the median is usually the mean between these two values (this method thus excludes ordinal characters).

The R function to calculate the median, **only for numerical data**, is `median()`.

```r
> median(x)
[1] 163
```

**Tip**

We propose the following code, which computes the median for *individual* ordinal or numerical data:

```r
> my.median <- function(x) {
+   if (is.numeric(x)) return(median(x))
+   if (is.ordered(x)) {
+     N <- length(x)
+     if (N%%2) return(sort(x)[(N+1)/2]) else {
+       inf <- sort(x)[N/2]
+       sup <- sort(x)[N/2+1]
+       if (inf==sup) return(inf) else return(c(inf,sup))
+     }
+   }
+   stop("Cannot calculate the median for this type of data.")
+ }
> my.median(fish)
```
Now suppose that we do not have individual data, but only the table of observed frequencies $f_1, \ldots, f_k$ in the $K$ classes $[e_0, e_1], \ldots, [e_{k-1}, e_k], \ldots, [e_{K-1}, e_K]$ of a quantitative variable. In that case, we need a linear interpolation between the two values with cumulative frequencies closest to 50%. Let $e_k$ and $e_{k+1}$ be the two consecutive values of class boundaries such that $\text{CFP}_X(e_k) < 0.5 \leq \text{CFP}_X(e_{k+1})$, where $\text{CFP}_X(e_j) = f_1 + f_2 + \ldots + f_j$, $j = 1, \ldots, K$ ($\text{CFP}_X(x)$ is the value of the cumulative frequency polygon at point $x$). Then:

$$m_x = e_k + (e_{k+1} - e_k) \times \frac{0.5 - \text{CFP}_X(e_k)}{\text{CFP}_X(e_{k+1}) - \text{CFP}_X(e_k)}.$$ 

We propose the following code to compute the median in such a case:

```r
> median.for.freq <- function(x) {
+   # x is the frequency table.
+   if (all(is.numeric(names(x)))) {
+     tab.freq.cum <- cumsum(x)
+     index <- order(tab.freq.cum < 0.5)[1]
+     fc1 <- tab.freq.cum[index]
+     fc2 <- tab.freq.cum[index-1]
+     x1 <- as.numeric(names(fc1))
+     x2 <- as.numeric(names(fc2))
+     mex <- as.numeric(x1 + (x2-x1) * (0.5-fc1)/(fc2-fc1))
+   } else {mex <- NA}
+   return(mex)
+ }
```

Here is how we compute the median for the data in vector $x$ grouped into classes with the function hist():

```r
> res <- hist(x,plot=FALSE,breaks=c(130,150,160,170,180,190))
> tab.x <- table(rep(res$breaks[-1],res$counts))
> median.for.freq(tab.x/sum(tab.x))
[1] NA
```

### 9.4.1.3 Mean

It can only be computed for quantitative variables.

```r
> mean(x)  # $\mu_x = \frac{1}{n} \sum_{i=1}^{n} x_i$
[1] 163.9602
```
9.4 Numerical summaries

9.4.1.4 Fractiles

The fractile of order \( p \) (\( 0 < p < 1 \)) is the value \( q_p \) of the variable \( X \) which splits the sample into two parts, one of size equal to \( p \% \) of the total sample size of \( x \) (elements smaller than \( q_p \)), the other of size \((1 - p) \% \) (elements greater than \( q_p \)). It cannot be computed for purely qualitative variables.

Fractiles of order 10 \% and 90 \%:

\[ \text{> quantile}(x, \text{probs}=c(0.1, 0.9)) \]
\[ \text{10\% 90\%} \]
\[ 153 176 \]

Quartiles \( q_{1/4}, q_{1/2}, q_{3/4} \) (also denoted as \( q_1, q_2 = m_e, q_3 \)):

\[ \text{> quantile}(x, \text{probs}=c(0.25, 0.5, 0.75)) \]
\[ \text{25\% 50\% 75\%} \]
\[ 157 163 170 \]

Deciles:

\[ \text{> quantile}(x, \text{probs}=1:10/10) \]
\[ \text{10\% 20\% 30\% 40\% 50\% 60\% 70\% 80\% 90\% 100\%} \]
\[ 153.0 156.0 158.5 160.0 163.0 165.0 168.0 172.0 176.0 188.0 \]

Tip

The function \( \text{summary()} \) applied to a vector of quantitative data calculates the minimum, maximum, mean and the three quartiles.

9.4.2 Summaries of the dispersion of a distribution

These summaries can only be computed for quantitative variables. We first define the following three \( R \) functions, then present the summaries in the next table.

\[ \text{> # Variance } \sigma^2 \text{ of the population } \sigma^2(x) = \frac{1}{N} \sum_{i=1}^{N} (x_i - \mu_X)^2. \]
\[ \text{> var.pop <- function(x) var(x)*(length(x)-1)/length(x)} \]
\[ \text{> # Standard deviation } \sigma \text{ of the population } \sigma(x) = \sqrt{\frac{1}{N} \sum_{i=1}^{N} (x_i - \mu_X)^2}. \]
\[ \text{> sd.pop <- function(x) sqrt(var.pop(x))} \]
\[ \text{> # Coefficient of variation: } \]
\[ \text{# \( c_v = \frac{\sigma}{\mu}. \)} \]
\[ \text{> co.var <- function(x) sd.pop(x)/mean(x)} \]
### Descriptive statistics

#### Note

An unbiased estimator \( \hat{\sigma}^2 \) of the variance \( \sigma^2 \) of a population, based on a sample of size \( n \), can be computed with the function `var()`. The corresponding standard deviation \( \hat{\sigma} \) is computed with the function `sd()`.

```r
> var(x) # \( \hat{\sigma}^2(x) = \frac{1}{n-1} \sum_{i=1}^{n} (x_i - \bar{x})^2 \)
# with \( \bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i \).
[1] 81.06063
> sd(x) # \( \hat{\sigma}(x) = \sqrt{\frac{1}{n-1} \sum_{i=1}^{n} (x_i - \bar{x})^2} \)
# with \( \bar{x} = \frac{1}{n} \sum_{i=1}^{n} x_i \).
[1] 9.003368
```

#### 9.4.3 Summaries of the shape of a distribution

These summaries can only be computed for quantitative variables. It is worth mentioning coefficients of asymmetry (skewness) and of peakedness (kurtosis); the relevant R code is given below.

```r
> skew <- function(x) mean((x-mean(x))^3)/sd.pop(x)^3
> skew(x) # \( \gamma_1 = \frac{\mu_3}{\sigma^3} \)
# with \( \mu_3 = \frac{1}{N} \sum_{i=1}^{N} (x_i - \mu_X)^3 \).
[1] 0.4256203
> kurt <- function(x) mean((x-mean(x))^4)/sd.pop(x)^4
> kurt(x) # \( \beta_2 = \frac{\mu_4}{\sigma^4} \)
# with \( \mu_4 = \frac{1}{N} \sum_{i=1}^{N} (x_i - \mu_X)^4 \).
[1] 2.778185
```

#### Tip

The functions `skewness()` and `kurtosis()` from package `moments` perform the same operations.
9.5 Measures of association

9.5.1 Measures of association between two qualitative variables

9.5.1.1 Pearson’s \( \chi^2 \) statistic

The results of this section are obtained with the function `chisq.test()`. We present how to compute the contingency table of observed counts \( O_{ij} \), the contingency table of theoretical (expected) counts \( E_{ij} \) (1 \( \leq i \leq p \), 1 \( \leq j \leq q \) (also called independence table), the table of contributions to the \( \chi^2 \) as well as the \( \chi^2 \) itself.

```r
> genderfat <- table(gender,fat) # Observed contingency table
> tab.ind <- chisq.test(genderfat)$expected # The \( E_{ij} \).
> round(tab.ind)

<table>
<thead>
<tr>
<th>fat</th>
<th>butter</th>
<th>margarine</th>
<th>peanut</th>
<th>sunflower</th>
<th>olive</th>
<th>Isio4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Male</td>
<td>6</td>
<td>10</td>

<td>0.928650954</td>
</tr>
</tbody>
</table>
> chi2 <- chisq.test(genderfat)$statistic # sum(tab.contr)
> chi2

X-squared
15.15842

Tip

Another way to compute Pearson’s \( \chi^2 \) statistic is to use the function `summary()`.

```r
> chi2 <- summary(table(gender,fat))$statistic
> chi2

[1] 15.15842
9.5.1.2 $\Phi^2$, Cramér’s $V^2$ and Pearson’s contingency coefficient

All indicators in the next table are computed from the $\chi^2$ coefficient.

```
> N <- sum(genderfat)
> p <- nrow(genderfat)
> q <- ncol(genderfat)
```

<table>
<thead>
<tr>
<th>Indicator</th>
<th>Formula</th>
<th>Instruction R</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\Phi^2$</td>
<td>$\Phi^2 = \frac{\chi^2}{N}$</td>
<td>$\text{Phi2} \leftarrow \text{chisq}(\chi^2)$</td>
<td>0.067</td>
</tr>
<tr>
<td>Cramér’s $V^2$</td>
<td>$V^2 = \frac{\Phi^2}{\min(p,q)-1}$</td>
<td>$\text{Phi2}/(\min(p,q)-1)$</td>
<td>0.067</td>
</tr>
<tr>
<td>Pearson’s contingency coefficient</td>
<td>$C = \sqrt{\frac{\chi^2}{N(N+\chi^2)}}$</td>
<td>$\sqrt{\chi^2/(N+\chi^2)}$</td>
<td>0.251</td>
</tr>
</tbody>
</table>

**Tip**

The function `cramer.v()` from package `rgrs` can also be used to compute Cramér’s $V^2$.

```
> require(rgrs)
> cramer.v(genderfat)^2
[1] 0.06707265
```

9.5.2 Measures of association between ordinal variables (or ranks)

9.5.2.1 Kendall’s $\tau$ and $\tau_b$

This coefficient is based on the notion of concordance of individuals. For two individuals $i$ and $j$ and for ordinal variables $X$ and $Y$ having $p$ and $q$ modalities respectively, pairs $(x_i, y_i)$ and $(x_j, y_j)$ are said to be concordant if $\text{sign}(x_j - x_i) = \text{sign}(y_j - y_i)$ and discordant if $\text{sign}(x_j - x_i) = -\text{sign}(y_j - y_i)$.

If $x_i = x_j$ or $y_i = y_j$ (or both), the corresponding pair is neither concordant nor discordant: we say there is a tie. If there are $n_c$ concordant pairs, $n_d$ discordant pairs and $n_t$ ties, then $n_c + n_d + n_t = \frac{1}{2}N(N-1)$.

Kendall’s $\tau_b$ is then given by the formula:

$$\tau_b = \frac{2(n_c - n_d)}{\sqrt{(N^2 - \sum_{k=1}^{p} n_k^2)(N^2 - \sum_{l=1}^{q} n_l^2)}}$$

where $2(n_c - n_d) = \sum_{k=1}^{p} \sum_{l=1}^{q} \text{sign}(x_k - x_l)\text{sign}(y_k - y_l)$, $n_{\bullet} = \sum_{l=1}^{q} n_{\bullet l}$ and $n_{\bullet l} = \sum_{k=1}^{p} n_{k l}$, with $n_{k l}$ being the number of individuals having the modalities $k$ for $X$ and $l$ for $Y$. 
When there are no ties, this formula simplifies to what is known as Kendall’s $\tau$:

$$\tau = \frac{2(n_c - n_d)}{N(N - 1)}.$$  

These two quantities can be computed in R with the function `cor()`.

```r
> cor(as.numeric(meat),as.numeric(fish),method="kendall")
[1] -0.1583088
```

Tip

Note that you could also compute these coefficients yourself by translating the formula for $\tau$ into R instructions:

```r
> Kendall.taub <- function(x,y) {
+   a1 <- sign(outer(as.numeric(x),as.numeric(x),"-"))
+   a2 <- sign(outer(as.numeric(y),as.numeric(y),"-"))
+   num <- sum(a1*a2)
+   N <- length(x)
+   b1 <- sum(margin.table(table(x,y),1)^2)
+   b2 <- sum(margin.table(table(x,y),2)^2)
+   denom <- sqrt((N^2-b1) *(N^2-b2))
+   taub <- num / denom
+   return(taub)
+ }
> Kendall.taub(meat,fish)
[1] -0.1583088
```

### 9.5.2.2 Spearman’s rank correlation coefficient $\rho$

First compute the ranks (function `rank()`) $x_i$ and $y_i$ of all individuals for variables $X$ and $Y$. In case of a tie, assign to tied values the rank equal to the mean of their shared positions (which is what the function `rank()` does by default).

When there are no ties, Spearman’s rank correlation coefficient is given by the formula

$$\rho = 1 - \frac{6 \sum_{i=1}^{N} d_i^2}{N(N^2 - 1)} \quad \text{with } d_i = x_i - y_i.$$  

When there are ties, we need to use the Pearson’s standard correlation coefficient between ranks:

$$\rho = \frac{N(\sum_{i=1}^{N} x_i y_i) - (\sum_{i=1}^{N} x_i)(\sum_{i=1}^{N} y_i)}{\sqrt{N(\sum_{i=1}^{N} x_i^2) - (\sum_{i=1}^{N} x_i)^2} \sqrt{N(\sum_{i=1}^{N} y_i^2) - (\sum_{i=1}^{N} y_i)^2}}.$$
To compute Spearman’s rank correlation coefficient in R, you can use the functions `rank()` and `cor()`, or use directly the function `cor()` with the argument `method` set to “spearman”.

```r
> cor(rank(fat),rank(situation))
[1] 0.008787643
> cor(as.numeric(fat),as.numeric(situation),method="spearman")
[1] 0.008787643
```

### 9.5.3 Measures of association between two quantitative variables

#### 9.5.3.1 Covariance and Pearson’s correlation coefficient

For two quantitative variables, the appropriate measure of association is correlation. It is defined as the ratio of the covariance of the two variables and their respective standard deviations. It is computed with the function `cor()`.

```r
> cor(height,weight)
[1] 0.6306576
```

Covariance is computed with the function `cov()`.

```r
> cov(height,weight)
[1] 68.32596
```

**Tip**

This coefficient can also be computed with the function `cor.test()`.

```r
> cor.test(height,weight)$estimate
cor
0.6306576
```

### 9.5.4 Measures of association between a quantitative variable and a qualitative variable

#### 9.5.4.1 Correlation ratio $\eta^2_{FIX}$

The correlation ratio $\eta^2_{FIX}$ indicates how much of the variation of the quantitative variable $Y$ is explained by the levels of the qualitative variable $X$ with $p$ levels. Indeed, $X$ can be viewed as defining groups in the population. The correlation ratio is the ratio of variance within groups and inter-group variance. It is given by the formula
\[ \eta^2_{Y \mid X} = \frac{\sum_{k=1}^{p} n_k (\bar{y}_k - \bar{y})^2}{\sum_{i=1}^{N} (y_i - \bar{y})^2} \]

where \( n_k \) denotes the number of observations \( y_i \) corresponding to the \( k \)th level of \( X \).

Here is the R code to compute this ratio:

```r
> eta2 <- function(x, gpe) {
+   means <- tapply(x, gpe, mean)
+   counts <- tapply(x, gpe, length)
+   varwithin <- (sum(counts * (means - mean(x))^2))
+   vartot <- (var(x) * (length(x) - 1))
+   res <- varwithin/vartot
+   return(res)
+ }
```

We compute it for the variables weight and gender.

```r
> eta2(weight,gender)
[1] 0.3325501
```

Tip

You can also use the following R instruction to compute \( \eta^2_{Y \mid X} \):

```r
> summary(lm(weight~gender))$r.squared
[1] 0.3325501
```

SECTION 9.6  
Graphical representations

The way a variable is represented graphically should always be adapted to the type of variable. Indeed, the type of a variable often translates into specificities of a plot. For instance, an arrow head at the end of an axis indicates that the corresponding levels are ordered. The direction of the axis of levels should thus be made evident for all variables, except those of a qualitative type. We have thus defined (and included in the package associated with this book) the function `arrowaxis()` which we shall use, when needed, to add an arrow on a plot axis. For some plots, we have decided to show side by side a basic version and a more elaborate and aesthetically pleasing version. We do not necessarily recommend using the elaborate version in data exploration, but these plots show the possibilities offered by R to modify a plot as one wishes.
9.6.1 Plotting qualitative variables

9.6.1.1 Cross chart

For each observation, the cross chart shows a small horizontal bar in the column of the relevant level. This diagram is not included in R, but it can be coded with the function `plot()` and its argument `pch`. The corresponding function, which we call `crosschart()`, is included in the package associated with this book.

```
> crosschart(situation,col=c("orange","darkgreen","black","tan"))
```

![Cross chart of variable situation](image)

Fig. 9.2: Cross chart for a qualitative variable.

Note that there also exists a function `dotchart()`. When coupled with the function `table()`, it gives a similar display, except that it is rather a representation of the table of counts of the variable.
9.6 Graphical representations

```r
> dotchart(table(situation), col = c("orangered", "darkgreen", "turquoise", "tan"), pch = 15, main = paste("Dot chart of counts", "of variable situation", sep = "\\n"))
```

![Dot chart of counts of variable situation](image)

Fig. 9.3: Dot chart for a qualitative variable.

### 9.6.1.2 Bar charts

It is obtained with the function `barplot()`. To make the plot prettier, we propose the function `barchart()`, included in the package associated with this book.

```r
> col <- c("gray", "orangered", "lightgoldenrodyellow", "red")
> barplot(table(situation), col = col)
```

![Bar chart for a qualitative variable](image)

Fig. 9.4: Bar chart for a qualitative variable.
9.6.1.3 Pareto chart

A Pareto chart can also be produced with the function barplot(), since it is a bar chart with bars ordered from tallest to smallest.

```r
> col <- c("yellow", "yellow2", "sandybrown", "orange",
+         "darkolivegreen", "green", "olivedrab2", "green4")
> barplot(sort(table(fat), T), col=col)
```

Fig. 9.5: Pareto chart for a qualitative variable.

```r
> barchart(fat, col, pareto=TRUE)
```
### 9.6.1.4 Stacked bar chart

A stacked bar chart can be obtained with the function `barplot()` with an object of type `matrix` as first effective argument.

```r
> nbh <- table(gender)[1]
> nbf <- table(gender)[2]
> tabfreq.fat.males <- table(fat[gender=='Male'])/nbh
> tabfreq.fat.females <- table(fat[gender=='Female'])/nbf
> barplot(cbind(tabfreq.fat.males,tabfreq.fat.females),
+ main="Stacked bar chart for variable fat",col=
+ c("yellow","yellow2","sandybrown","orange",
+ "darkolivegreen","green","olivedrab2","green4"),xlim=
+ c(0,1),width=0.15,space=1,names.arg=
+ c("Males","Females"),legend=TRUE,density=40)
> arrowaxis(x=F,y=T)
```

Fig. 9.6: Stacked bar chart for a qualitative variable.
9.6.1.5 Pie chart

A pie chart can be obtained with the function `pie()`. We propose the more aesthetically pleasing function `camembert()`, included in the package associated with this book.

> require("RColorBrewer")
> col <- brewer.pal(8,"Pastel2")
> `pie(table(fat), col=col)`

---

> `camembert(fat, col)`

**Pie chart for variable fat**

- olive (18%)
- sunflower (30%)
- peanut (21%)
- margarine (12%)
- Isio4 (10%)
- lso4 (10%)
- butter (7%)
- duck (2%)
- rapeseed (1%)

---

9.6 Graphical representations
9.6.2 Plotting ordinal variables

9.6.2.1 Bar chart with cumulative frequencies line

Such a chart can be obtained with the functions `barplot()` and `points()`. As previously, the function `barchart()` included in the package associated with this book allows a different representation (for instance, the line of cumulative frequencies is raised and projects a shadow).

```r
> require("RColorBrewer")
> col <- brewer.pal(6,"Blues")
> tx <- table(fish)
> tx <- tx/sum(tx)
> r <- barplot(tx,ylim=c(0,1),col=col)
> points(r,cumsum(tx),type="l")
```

Fig. 9.7: Bar chart with cumulative frequencies line for an ordinal variable.

9.6.3 Plotting discrete quantitative variables

9.6.3.1 Cross chart

A cross chart can be obtained with the function `crosschart()`, included in the package associated with this book.
9.6 Graphical representations

363

See also

See the section on qualitative variables, page 356.

9.6.3.2 Bar chart
Such a chart can be obtained with the function plot() applied to a contingency
table.
> plot(tabtea/length(unique(tea)),ylab="",
+
col="darkolivegreen",lwd=5,
+
main="Bar chart for variable tea")
> arrowaxis()

Fig. 9.8: Bar chart for a discrete quantitative variable.

9.6.3.3 Plotting the empirical distribution function
Such a plot is obtained with the functions plot() and ecdf().


364 9 Descriptive statistics

> plot(ecdf(na.omit(coffee)), main=paste("Empirical distribution function", + " for variable coffee", sep="\n"), verticals=TRUE, + ylab=expression(F[n](x)), col.01line="#89413A", col.points= + "#6D1EFF", col.hor=`#3971FF`, col.vert=`#3971FF`) + arrowaxis(x=T, y=T)

Fig. 9.9: Empirical distribution function for a discrete quantitative variable.

9.6.3.4 Stemplot

A stemplot, or stem-and-leaf display, can be obtained with the function stem.leaf() of package aplpack.

See also

See the section on continuous quantitative variables, page 367.

9.6.3.5 Boxplot

Such a chart can be obtained with function boxplot(), as shown below. The chart gives explanations.
> boxplot(coffee, col="orange",
+ main="Boxplot for variable coffee")
> arrowaxis(x=F, y=T)

![Boxplot for variable coffee](image)

Fig. 9.10: Boxplot and explanations.
The box is drawn using the values of the three quartiles. Values represented as small circles are outliers, which might be suspect or deviant (boxplot(cafe)$out). These extreme values are those that are outside the box, further than 1.5 times the interquartile range (the argument range can be used to change this value from the default 1.5). Note that values which are outside the box, but within 1.5 times the interquartile range, are called adjacent values. The whiskers are drawn at the largest and smallest adjacent value.

Tip
Type example(bxp) or example(boxplot) for other examples of such diagrams.

9.6.4 Plotting continuous quantitative variables

We now present a few useful graphs for exploring quantitative data.

9.6.4.1 Empirical distribution function

Use the functions plot() and ecdf().
9.6 Graphical representations 367

> plot(ecdf(na.omit(age)),main=paste("empirical distribution function", +  "of variable age",sep="\n"),col.hor='# 3971FF',col.points='#3971FF')
> arrowaxis()

![Empirical distribution function of variable age](image)

Fig. 9.11: Plot of the empirical distribution function for a continuous quantitative variable.

9.6.4.2 Stemplot

You can use the function `stem()`, but it is not very sophisticated. We recommend the function `stem.leaf()` from package `aplpack`. Chart construction is done in three steps:

- choose a leaf unit, using argument `unit`;
- choose the number of parts (1, 2 or 5) in which each stem should be divided, using argument `m`;
- choose the representation style, using argument `style` which can take the values "Tukey" or "bare".

```r
> require(aplpack)
> stem.leaf(height,m=5,style="bare")

1 | 2: represents 12
leaf unit: 1
n: 226
1 14 | 0
14 |
14 |
14 |
3 14 | 88
12 15 | 000001111
24 15 | 222223333333
```
9.6.3 Boxplots

They can be created with the function `boxplot()`.

See also

See the section on discrete quantitative variables, page 364.

9.6.4.4 Density histogram with identical or different class ranges

Use the function `hist()`.

```r
> classes <- hist(age, right=T, freq=F, ylab="Density",
+ main="Histogram of variable age", col="orangered")
> arrowaxis()
```
9.6 Graphical representations

Histogram of variable age

Histogram of variable weight

> classes <- hist(weight, right=T, freq=F, 
+ main="Histogram of variable weight", 
+ ylab="Density", breaks=c(min(weight), 50, 80, 
+ 90, max(weight)), col="olivedrab")
> arrowaxis()

Fig. 9.12: Density histogram with identical or different class ranges.

9.6.4.5 Frequency polygon

Use the functions hist() and segments().
9.6.4.6 Cumulative frequency polygon

Use the functions `hist()`, `ecdf()` and `plot()`.

```r
> bounds <- hist(height, right=T, plot=F)$breaks
> plot(bounds, ecdf(height)(bounds), type="l", main=
+   paste("Cumulative frequency polygon", "of variable height", sep="\n"),
+   ylab="Frequencies", col="darkolivegreen", lwd=3)
> arrowaxis()
```

Fig. 9.14: Cumulative frequency polygon.
9.6 Graphical representations

9.6.5 Graphical representations in a bivariate setting

In this section, we present a few useful representations for bivariate settings.

9.6.5.1 Two-way plots for two qualitative variables

You can overlay two barplots, as shown on the next two figures.

```r
> tss <- prop.table(table(gender,situation),1)

> barplot(tss,bes=T,leg=T)
> title(paste("Barplots of situation","as a function of gender",
+ sep="\n"))
> arrowaxis(F,T)
```

![Barplots of situation as a function of gender](image)

Fig. 9.15: Bar plot for two qualitative variables.

A mosaic plot can also be useful to visualize the relationship between two qualitative variables.
> par(las=1) # Horizontal writing of levels.
> mosaicplot(gender~fat,color=brewer.pal(5,"Set1"),
>          main="Mosaicplot of fat as a function of age")

Fig. 9.16: Mosaic plot for two qualitative variables.

Tip

Another interesting function in this setting is assocplot() which produces a Cohen-Friendly association plot indicating deviations from independence in a $2 \times 2$ contingency table. We can also cite the function spineplot().

> assocplot(table(gender,fat))

Fig. 9.17: Cohen-Friendly association plot for two qualitative variables.

One last interesting function is table.cont() from package ade4.
9.6 Graphical representations

```r
> require(ade4)
> genderfat <- table(gender,fat)
> table.cont(genderfat,row.labels=rownames(genderfat),
+ col.labels=colnames(genderfat))
```

Fig. 9.18: `table.cont` plot for two qualitative variables.

### 9.6.5.2 Two-way plots for two quantitative variables

In this setting, use the function `plot()`.

```r
> plot(height~weight)
> arrowaxis()
```

We have seen in Chapter 5 how to make this plot prettier. To this end, we create a function `flashy.plot()`.

````
9.6.5.3 Two-way plots for one qualitative and one quantitative variable

In this setting, it is interesting to draw box plots of the quantitative variable for each level of the qualitative variable. If the variables are structured correctly in R, you simply need to call the function `plot()`. 

---

Fig. 9.19: Plot of two quantitative variables.
> par(bty="n")
> plot(coffee~gender, col=brewer.pal(5,"Set2"), notch=T, varwidth=T,
>       boxwex=0.3)
> title(paste("Boxplot of coffee consumption",
> + "as a function of gender", sep="\n"), family="Courier")
> arrowaxis(F,T)

Fig. 9.20: Box plots of a quantitative variable as a function of the levels of a qualitative variable.

Also note that the function `stripchart()` is useful to get the following plot:

> stripchart(raw_fruit~age, data=nutrielderly)
> arrowaxis(y=T)

Fig. 9.21: `stripchart` plot for a quantitative and a qualitative variable.
Memorandum

as.factor(): transform a variable into factors
levels(): display or affect the levels of a factor
as.ordered(): transform a variable into ordered factors
as.integer(): structure a discrete variable
as.double(): structure a continuous variable
table(): table of counts for a variable, or contingency table between two variables
addmargins(): add margins to a contingency table
margin.table(): marginal distributions of a contingency table
prop.table(): conditional distributions from a contingency table
na.omit(): remove missing values (NA) of a variable
median(): median of a vector
mean(): mean of a vector
quantile(): quantiles of a vector
summary(): when applied to a numerical series, returns minimum, maximum, quartiles and mean
range(): minimum and maximum
IQR(): interquartile range
var(): variance of a sample
sd(): standard deviation of a sample
mad(): absolute deviation from the median
chisq.test(): chi-squared statistic
cor.test(): Pearson’s correlation coefficient, Kendall’s τ or Spearman’s ρ
cov(): covariance
cor(): correlation
barplot(): draw a bar chart
pie(): draw a pie chart
plot.ecdf(): plot the empirical cumulative distribution function
stem(): draw a stem plot
boxplot(): draw a box plot
hist(): draw a histogram
plot(): draw a scatter plot

Exercises

9.1- Give the instruction which returns the table of frequencies for a qualitative variable x.
9.2- Give the instruction which returns the contingency table for qualitative variables x and y.
9.3- Which function returns the marginal distributions from a contingency table?
9.4- Which function returns the conditional distributions from a contingency table?
9.5- Give the instruction which returns the mode of a distribution.
9.6- Give the instruction which returns the range of a vector x.
9.7- Give the instruction which returns the interquartile range of a vector x.
Give the instruction which returns the (non empirical) variance of a vector $x$.

Give the code of a function which calculates the coefficient of variation.

Give the instruction which calculates the mean absolute deviation.

Which package includes functions to calculate skewness and kurtosis?

Give the instruction which returns Cramér’s $\Phi^2$.

Give the code of a function which calculates the correlation ratio $\eta^2_{Y\mid X}$.

Which function would you use to draw a Pareto chart?

Which function would you use to draw a stacked bar chart?

Which function would you use to draw a pie chart?

Which function would you use to draw a box plot?

Which function would you use to draw a histogram?

---

Worksheet

Descriptive data studies

A - Thoughts on independence in descriptive statistics

Import the file http://www.biostatisticien.eu/springeR/snee74en.txt into an R object called snee.

Display the first and last lines of snee with the functions `head()` and `tail()`. How many individuals are there? How many variables? What type are the variables?

Use the function `attach()` on your data.frame then check with the functions `class()` and `levels()` that the structure of your variables is correct. What are the levels of the variables?

Perform a univariate descriptive study of each variable: numerical results and appropriate graphical representations.

We shall now study the dependence of variables eyes and hair. Create the contingency table `eyeshair` (observed counts) of variables eyes and hair.

Calculate the frequency of each level of the variable hair (profile by column). You get the distribution function $f_{\text{hair}}$ of hair colour in the population.

Now, include the second characteristic: eye colour. Calculate the number `nblue` of individuals with blue eyes in the entire population.

Suppose that eye colour and hair colour are independent. In other words, the fact that an individual has blue eyes bears no relation with the colour of their hair. In that case, the proportions calculated in 9.6 should still be the same within the subpopulation of people with blue eyes. Under this independence hypothesis, calculate the number of blue-eyed people who should have blond hair (respectively brown, black and red).

Do the same with other eye colours. You get a table `tab.ind1` of theoretical counts under the hypothesis of independence between eye and hair colour.
9.10- Repeat the entire process, but with the two characteristics inverted (i.e. start with the variable eyes). From table eyeshair, calculate the frequency of each level of the variable eyes (profiles by rows). You get the distribution function feyes of eye colours in the population.

9.11- Now include the second characteristic: hair colour. Calculate the number nb1ond of people with blond hair in the entire population.

9.12- Suppose that hair and eye colour are independent. In other words, the fact that an individual has blond hair bears no relation with their eye colour. In that case, the proportions calculated in 9.10 should still be the same within the subpopulation of people with blond hair. Under this independence hypothesis, calculate the number of blond people who should have blue eyes (respectively brown, hazel and green).

9.13- Do the same with other hair colours. You get a table tab.ind2 of theoretical counts under the hypothesis of independence between hair and eye colour.

9.14- Use the function all.equal() to compare the two tables of theoretical counts. What do you observe?

9.15- Compare the table of observed counts eyeshair with the table of theoretical counts (for each entry, calculate the square of the difference).

9.16- Calculate the table of contributions to the $\chi^2$.

9.17- Calculate all relevant link indicators. Conclude.

9.18- Independence can also be defined (and this is in fact the primary definition) as equality of all conditional distributions. Calculate the conditional distribution of the variable hair knowing that the eye colour is blue (i.e. the frequency of various hair colours knowing that eye colour is blue). Calculate the three other conditional distributions of the variable hair. Calculate the conditional distributions of the variable eyes knowing each of the levels of variable hair. Conclude.

9.19- Perform a descriptive study of variable hair as a function of variable gender.

9.20- Perform a descriptive study of variable eyes as a function of variable gender.

9.21- Analyze the dependence between eye colour and hair colour for the following contingency table:

<table>
<thead>
<tr>
<th>Hair</th>
<th>Blond</th>
<th>Brown</th>
<th>Black</th>
<th>Red</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Eyes</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Blue</td>
<td>1 768</td>
<td>807</td>
<td>189</td>
<td>47</td>
<td>2 811</td>
</tr>
<tr>
<td>Grey/green</td>
<td>946</td>
<td>1 387</td>
<td>746</td>
<td>53</td>
<td>3 132</td>
</tr>
<tr>
<td>Brown</td>
<td>115</td>
<td>438</td>
<td>288</td>
<td>16</td>
<td>857</td>
</tr>
<tr>
<td>Total</td>
<td>2 829</td>
<td>2 652</td>
<td>1 223</td>
<td>116</td>
<td>6 800</td>
</tr>
</tbody>
</table>

B- Descriptive analysis of data set NutriElderly

We now propose to solve the following questions on the dataset NutriElderly, in which deliberate errors were introduced.

9.1- Import the data file nutrition_elderly.xls.
9.2- Give the absolute mode of variables situation, chocol and height.
9.3- Choose classes for variable height and give the modal class.
9.4- Calculate the median of variable chocol.
9.5- Give frequency tables of variables chocol and raw_fruit.
9.6- Using only these frequency tables, give the median of these two variables.
9.7- Calculate the quartiles of variable height using the classes defined earlier.
9.8- Draw the cumulative frequency polygon for variable height. On this plot, estimate the quartiles of the distribution.
9.9- Using individual data, calculate the mean of variables height, weight and age.
9.10- Calculate the frequency table of variable tea. Using this table, calculate the mean of this variable.
9.11- Calculate the mean of variable height using the classes defined earlier.
9.12- Calculate the range of variable weight.
9.13- Draw a boxplot of variable weight.
9.14- Using individual data, calculate the standard deviation of variable height.
9.15- Using only its frequency table, calculate the coefficient of variation of variable tea.
9.16- Calculate the total variance, the within-group variance and the between-group variance of variable coffee with the population split into two groups: males and females. Calculate the coefficient $\eta^2$.

C- Descriptive analysis of data sets

9.1- Perform a descriptive statistical analysis of data set Birth-weight.
9.2- Perform a descriptive statistical analysis of data set Infarction.
Chapter 10
A better understanding of random variables, distributions and simulations using R specificities

Goals of this chapter
We use the specificities of R to build empirically the notions of random variable, distribution of a random variable, law of large numbers and central limit theorem. We introduce some complex notions for statistical inference and examine sampling variation as well as the bias and variance of estimators. We go on to describe a few classical methods for simulating from a distribution. At the end of the chapter, we give commands to generate observations from common probability distributions and to calculate their probability and cumulative distribution functions and quantiles.

SECTION 10.1
Notions on random number generation

Consider an urn containing \( n \) balls numbered 1 to \( n \). Random number construction can be imagined as an experience in which we pick (or draw) with replacement a single ball at a time, several times in a row. This operation produces a sequence of integers. The order in which these numbers appear is governed by a law called the discrete uniform distribution (on the set \( \{1, \ldots, n\} \)). It is then natural to wonder how to generate real numbers uniformly over an interval. We introduce a few elements on number generation from such a uniform distribution, using a computer algorithm.

Random number generation is an essential part of simulation. The production of such numbers can be based on a mathematical algorithm which imitates randomness. We now explore such an algorithm ([34]), based on linear congruence, with period \( 2^{31} - 1 \).
The algorithm is defined by an initial value $x_1$, chosen arbitrarily over $[0, 1]$ and called the seed of the generator, by the constant $m = 2^{31} - 1$ and by the following recurrence relation:

\[
\begin{align*}
    x_1 & \leftarrow \text{arbitrary value in } [0, 1] \\
    x_2 & \leftarrow 48271 \times x_1 \pmod{m} \\
    x_2 & \leftarrow x_2/m \\
    x_{j+1} & \leftarrow 48271 \times x_j \times m \pmod{m} \quad \forall j > 1 \\
    x_{j+1} & \leftarrow x_{j+1}/m \quad \forall j > 1
\end{align*}
\]

Recall that $x \pmod{m}$ represents the “remainder in the division of $x$ by $m$”.

Other similar algorithms are presented in Robert and Casella’s book ([35]).

**Do it yourself**

Give the sequence of R instructions which code this algorithm to create $n = 30$ values. Recall that $x \pmod{m}$ can be computed in R with the instruction `x%%m`.

The following vector `x` contains $n = 30$ values generated from this algorithm.

```
x =
[1] 0.278500000000 0.000006260105 0.302181537086
[4] 0.604976700582 0.830313805990 0.077728950753
[7] 0.054181800068 0.409671066650 0.232058248096
[10] 0.683693839119 0.585308108730 0.407716482275

```

As you can see, the values created by this algorithm are unpredictable (apart from the fact that they are between 0 and 1). However, because they were created with a deterministic mathematical algorithm, these values are called **pseudo-random** numbers.

The algorithm above is a pseudo-random number generator called `uniform` over $[0, 1]$, because it generates numbers spread uniformly over this interval.
Pseudo-random number generation is of course implemented at the core of \texttt{R}. For instance, a more elaborate version of the algorithm above is available through the \texttt{R} function \texttt{runif()}. The function \texttt{set.seed()} is used to set the seed of the algorithm.

SECTION 10.2

The notion of random variables

In the previous section, we proposed an algorithm to generate pseudo-random numbers. In Probability and Statistics, such a process is usually called a random variable. The purpose of this section is to propose a heuristic on this topic: a random variable could be viewed as an algorithm to generate numbers, which are then called realizations of the random variable.

10.2.1 Realizations of a random variable and functioning law

In this section, we shall see how the syntax of \texttt{R} can help us better understand the difference between a random variable and its realizations.

A common example is that a Statistics problem start with one of the following assertions: (1) “Let $X$ be a random variable with distribution $\mathcal{U}(0, 1)$” or (2) “Let $X$ be a random variable with distribution $\mathcal{N}(0, 1)$”.

A random variable can be viewed as a number creation factory or, in mathematical terms, as a function which creates a random number every time it is called. The process which creates values generated by a random variable is governed by a functioning rule imposed upon this variable, called the distribution of the random variable. This is shown clearly in the body of the function that defines it.

In \texttt{R}, it is easy (and informative) to create such random variables. For instance, the instruction

\begin{verbatim}
> X <- function() runif(1)
\end{verbatim}

corresponds to assertion (1). Successive calls of this function create realizations of the random variable $X$:

\begin{verbatim}
> X()
[1] 0.8806583
\end{verbatim}
Similarly, the instruction

```r
> X <- function() rnorm(1)
```

corresponds to assertion (2). Once again, successive calls of this function create realizations of the new random variable X:

```r
> X()
[1] 0.6683035
> X()
[1] -0.3708295
> X()
[1] 0.7179792
```

We find this makes it easier to understand the difference between a random variable (the function) and its realizations (the numbers output by the function). As you can see, a random variable is a “machine” (a procedure) which makes values, called realizations. It is random in the sense that the realizations change at each call, and that it is impossible to predict which value will be output.

**Warning**

Note that the two random variables we have introduced are built in the same way (the instructions are the same), except for the functioning rule or distribution which governs them (`runif` or `rnorm` in the body of the function).

### 10.2.2 I.i.d. random variables

Another standard statement in Statistics is: “Let $X_1, \ldots, X_n$ be $n$ independent and identically distributed (i.i.d.) random variables following the distribution $N(0, 1)$”.

This concept can easily be translated into R. For example, with $n = 4$, we get:

```r
> X <- function() rnorm(1) # r.v. governed by the distribution
# rnorm (i.e. N(0,1)).
> X4 <- X3 <- X2 <- X1 <- X # Translates the fact that
# X_i are i.i.d.
```

**Warning**

$X_1$ and $X_2$ follow the same distribution `rnorm`. They are identically distributed. However, they are not identical, in the sense that they do not produce the same values. Independence of $X_1$ and $X_2$ means the production of values by $X_1$ is not influenced by $X_2$: 
Note that you could also consider the vector $X = (X_1, \ldots, X_4)$, which is a random vector with four components and which produces four “independent” realizations simultaneously at each call.

```r
> vecX <- function() c(X1(),X2(),X3(),X4())
> vecX()
[1] 0.8041706 -3.6413500 1.7871627 0.7710802
> # or, equivalently in R:
> vecX <- function() rnorm(n = 4)
> vecX()
[1] -0.3010423 0.7895389 0.2059419 1.0169773
```

**Tip**

If the $n$ $X_i$ are i.i.d. with same distribution as $X$, then $X_n = (X_1, \ldots, X_n)$ can be created using:

```r
> vecXn <- function(n) replicate(n,X())
> vecXn()
```

The random vector $X_n = (X_1, \ldots, X_n)$ is called the **sample**.

### 10.2.3 Characterizing the distribution of a random variable

We have seen that the process by which a random variable produces values is governed by a **functioning rule**, called the **distribution** of the random variable.

**Note**

We shall use the standard symbol $\sim$ to indicate that a random variable $X$ follows a given distribution. For example, we shall write $X \sim U(0, 1)$ to indicate that the random variable $X$ follows a uniform distribution over the interval $[0, 1]$, or $X \sim N(0, 1)$ to indicate that $X$ follows a standard Normal distribution.

The next drawing illustrates the idea that a random variable is a “machine” governed by **parameters**, and which outputs realizations. There is a blueprint of the machine, which governs how the realizations are created. But slight, unpredicted
variations in the run of the process lead to variations in the output, which can therefore not be completely predicted. Indeed, each specific realization is unpredictable and governed by randomness. However, since there is a fixed functioning rule for the generator, it is still possible to describe a few global properties of these numbers. There are thus several kinds of randomness, each structured by the distribution of the random variable at play. When speaking of “random numbers”, it is necessary to specify the kind of randomness.

Mathematicians have introduced mathematical objects describing this structure: the probability density function (or density, or p.d.f.); the cumulative distribution function (or distribution function, or c.d.f.); and the quantile function of a random variable, to name a few. In most cases, these functions characterize completely the distribution of the random variable.

10.2.3.1 Density function, distribution function, quantile function

Suppose that we observe several unpredictable values produced by a random variable \( X \). We wish to describe these values and, through them, to better understand or specify the functioning of the generator \( X \).

Here are a few examples of what you might notice for a given random variable \( X \):

- there are positive and negative values;
- they are gathered around the number 7;
- as many values are greater than and lesser than 7;
- they are spread symmetrically about 7;
- and so on

On a more global scale, you can also look at the density of observations (in the common meaning of the word: a high density corresponds to values close to each
10.2 The notion of random variables

other) generated by \( X \) in intervals \([x - \epsilon, x + \epsilon]\) (where \( \epsilon \) is a very small non-negative number) of the range of possible values. The range of possible values is called the **support** of \( X \). The code of the function **density**, given below, was written for didactic reasons and is not efficient; it should help translate the notion of density of observations.

```r
> # The code (distribution) of the r.v. X is temporarily hidden
> # on purpose.
> X <- function() some.code(some,parameters)
> ourdensity <- function(x,n=1000,eps=0.01) {
+ lx <- length(x)
+ res <- vector("integer",lx)
+ obs <- replicate(n,X()) # Generate observations from X.
+ for (i in 1:lx) {
+   res[i] <-
+   length(which((x[i]-eps) <= obs & obs <= (x[i]+eps)))/n
+ }
+ return(res)
+ }
```

The plot below represents the function which associates to each interval in the support of \( X \) the value \( y \) of the relative concentration of observations in this interval (i.e. the frequency of values belonging to this interval).

```r
> curve(ourdensity,xlim=c(-1,10))
```

If you increase the number \( n \) of observations generated by \( X \) and decrease \( \epsilon \), this plot becomes smoother.

```r
> curve(ourdensity(x,n=1000000,eps=0.001),xlim=c(-1,10))
```
In the limit, as $n \to \infty$ and $\epsilon \to 0$, this plot becomes perfectly smooth and regular. Once normalized so that its area equals 1, it is called the density function of the random variable $X$ and is denoted $f_X$.

A random variable whose possible values can make a continuous set of values (such as an interval) is called continuous. A random variable which can only take a finite or countable number of different values (also called modalities) is called discrete. For a discrete random variable, we do not speak of its density, but of its mass function which gives the probability of outcome of each modality.

To sum up, it could be said that describing the distribution of a random variable $X$ consists in giving two pieces of information:

1) the range of possible values or support of $X$ (which can be discrete or continuous);
2) for each (infinitesimal) interval in this range, the value of the density of $X$ for a continuous random variable, or of the mass function of $X$ for a discrete random variable.
The cumulative distribution function \( F_X(x) \), which accumulates the densities of observations up to the point \( x \) (or which accumulates the observation probabilities of all modalities up to and including \( x \) for a discrete variable), is another way of characterizing the distribution of a random variable. It can be shown that it represents the area of the density plot \( f_X \) up to \( x \) and that it gives the probability that the random variable \( X \) creates observations smaller than \( x \):

\[
F_X(x) = P[X \leq x] = \int_{-\infty}^{x} f_X(t) \, dt.
\]

The quantile function \( F_X^{-1} \), the inverse distribution of the cumulative distribution function, also characterizes a random variable.

For each probability value \( p \in [0,1] \), the value \( x_p = F_X^{-1}(p) \) is called the fractile or quantile of order \( p \) of random variable \( X \). It is defined by the equation

\[
x_p = F_X^{-1}(p) \iff F_X(x_p) = P[X \leq x_p] = p.
\]

Thus, the probability that the realizations of the random variable \( X \) be lesser than or equal to the value \( x_p \) is \( p \). The following plot illustrates this notion.

10.2.4 Parameters of the distribution of a random distribution

We had deliberately hidden the body of the function defining the random variable \( X \). We can now reveal that the density shown on Figure 10.1 is the density of a random variable \( X \) following the distribution \( \mathcal{N}(\mu = 7, \sigma^2 = 1) \).
390 A better understanding of random variables, distributions and simulations using R specificities

```r
> X <- function() rnorm(1,7,1)
```

**Tip**

The R function `density()` gives the density plot of a sample of observed values.

```r
> plot(density(rnorm(1000,7,1)),xlim=c(-1,10),
+ main="Density plot with function density()")
```

![Density plot with function density()](image)

In this definition, the quantities $\mu = 7$ and $\sigma^2 = 1$ appear explicitly. They are called the **parameters** of this distribution.

Let $X_1, \ldots, X_n$ be $n$ independent and identically distributed (i.i.d.) random variables following the normal distribution with mean $\mu = 7$ and variance $\sigma^2 = 1$. We also define $\bar{X}_n = \frac{1}{n} \sum_{i=1}^{n} X_i$.

We have noticed that it is sometimes difficult to understand the (fundamental) difference that exists between:

- the random variable $\bar{X}_n$;
- its realizations $\bar{x}_n$;
- and the **parameter** $\mu = \mathbb{E}(X)$, which is the theoretical expectation.

It is true that, by abuse of language, these three objects are often all called by the same name: **the mean**.
We believe that the R language helps better understand and distinguish these concepts. The random variable $\bar{X}_4 = \frac{1}{4} \sum_{i=1}^{4} X_i$ (for $n = 4$) could be defined as:

```r
> X1 <- function() rnorm(1, mean = mu <- 7, sd = 1)
> X4 <- X3 <- X2 <- X1
> Xbar4 <- function() (X1()+X2()+X3()+X4())/4
```

Advanced users

The random variable $\bar{X}_n$ can be defined automatically (for small $n$):

```r
> n <- 10
> eval(parse(text=paste(paste("X",1:n," <- ",sep="",
+ collapse=""),"X"))))
> eval(parse(text=paste("Xbar","n"," <- function() + (",paste("X",1:(n-1)," +",sep="",collapse=""),
+ " X",n," ()/",n,sep=""))),
> Xbar10
function()
(X1()+X2()+X3()+X4()+X5()+X6()+X7()+X8()+X9()+X10())/10
```

This function can be used repeatedly to create several realizations, which could be denoted $\bar{x}_4^{(i)}$, $i = 1, 2, \ldots$:

```r
> xbar4.1 <- Xbar4()
> xbar4.1
[1] 7.495727
> xbar4.2 <- Xbar4()
> xbar4.2
[1] 7.069361
> xbar4.3 <- Xbar4()
> xbar4.3
[1] 6.837127
```

It is clear that successive calls of the same function `Xbar4()` result in several different unpredictable realizations which vary around 7: the $\bar{x}_4^{(i)}$. This helps show that:

- $\bar{X}_4$ is indeed a random variable, i.e. a machine to create realizations;
- the realizations $\bar{x}_4^{(1)}, \bar{x}_4^{(2)}, \bar{x}_4^{(3)}, \ldots$ are all different, unpredictable, and come from the random variable $\bar{X}_4$;
- the machine $\bar{X}_4$ is made of the individual random variables $X_1, \ldots, X_4$, which all follow the same functioning law;
- this functioning law depends on a parameter $\mu$ (affected to the formal parameter `mean` of the function `rnorm()`) which was set upon creation to the value $\mu = 7$, and which does not vary between calls of the function;
- the parameter $\mu$ is thus an intrinsic characteristic of each of the variables $X_i$. 

---

10.2 The notion of random variables

---
Since $\overline{X}_4$ is a random variable, it has a distribution, like any random variable. Mathematical theory states that $\overline{X}_4 \sim \mathcal{N}(\mu = 7, \sigma^2 = 1/4)$. If we only care about the behaviour of the distribution of $\overline{X}_4$, we can define it directly with:

```r
Xbar4 <- function() rnorm(1, mean = 7, sd = sqrt(1/4))
```

### SECTION 10.3

**Law of large numbers and central limit theorem**

Let $\overline{X}_n = \frac{1}{n} \sum_{i=1}^{n} X_i$ be the mean random variable made of $n$ i.i.d. random variables $X_i$, each following the same distribution $\mathcal{L}$ (which is not necessarily known) with expectation $\mathbb{E}(X_i) = \mu$ and variance $\text{Var}(X_i) = \sigma^2 < \infty$.

#### 10.3.1 Law of large numbers

The **law of large numbers** states that when $n$ goes to infinity, the mean random variable $\overline{X}_n$ goes (technical term: converges in probability) to $\mathbb{E}(X_1)$, i.e. the theoretical mean $\mu$. This is written $\overline{X}_n \xrightarrow{P} \mathbb{E}(X_1)$. This can easily be checked in R, for example when $\mathcal{L} = \mathcal{U}(0,1)$:

```r
> mean(runif(1))
[1] 0.2501903
> mean(runif(10))
[1] 0.3372082
> mean(runif(100))
[1] 0.5185887
> mean(runif(1000))
[1] 0.4885624
> mean(runif(10000))
[1] 0.5062192
> mean(runif(100000))
[1] 0.4998102
> mean(runif(1000000))
[1] 0.5000058
```

We notice that when the size of the sample $n$ increases, these numbers get closer to the theoretical mean $\mu = 0.5$ of the $n$ i.i.d. random variables $\mathcal{U}(0,1)$. 

```
10.3 Law of large numbers and central limit theorem

Note

This will be very useful to approximate (technical term: estimate) the unknown parameters of a distribution. We shall return to this point in Section 10.4.

10.3.2 Central limit theorem

We can also look at the random variable \( Y_n = \sqrt{n} \left( \bar{X}_n - \mu \right) / \sigma \) which is used as a pivot when constructing some confidence intervals and hypothesis tests. As all random variables, \( Y_n \) has a distribution. In some cases, mathematics allow us to calculate it explicitly. In general, this distribution depends on the size \( n \) of the sample. One might wonder how this distribution changes as \( n \) increases. This behaviour is called the convergence in distribution of a random variable. The central limit theorem states that \( Y_n \) converges in distribution to a random variable with distribution \( N(0, 1) \). In other words, generating observations from \( Y_\infty \) is equivalent (as far as one is only concerned with the distribution of the values of \( Y_\infty \)) to generating observations from a random variable with distribution \( N(0, 1) \).

This mode of convergence, as well as other classical modes of convergence (convergence in probability, almost sure, and in \( r \)-th order mean) are very well explained in [24].

The package ConvergenceConcepts, described in [23], is a tool to visualize this evolution graphically. For example, try the following instructions:

```r
require(ConvergenceConcepts)
iinvestigate() # Choose Example 3.
```
In the previous section, we saw that the law of large numbers can be used to approximate the fixed parameter (call it $\theta$) of a distribution thanks to the realization of a random variable (for example, the parameter $\mu$ thanks to a realization of $X_n$). This will of course be very useful when the parameter is unknown. The “approximating” random variable is then called an estimator of the parameter. Realizations of this estimator are called estimates (of the unknown parameter $\theta$). To perform inference is to estimate unknown parameters based on a sample of random variables which follow a distribution which depends on these unknown parameters.

\section*{10.4.1 Point estimate of parameters}

What is an estimator? Since we are proposing a plausible value for the unknown parameter of a distribution, based on a sample generated from this distribution, we can consider this plausible value as a function of the sample. If $\theta$ is the unknown
10.4 Inferential statistics

value of the parameter to guess (estimate), we note our proposition \( \hat{\theta}(x_1, \ldots, x_n) \), thus specifying explicitly that it depends on the values of our sample. We call it an estimate of \( \theta \).

Then \( \hat{\theta}(X_1, \ldots, X_n) \) is the estimator of \( \theta \). This estimator is a random variable, a function of the random variables which generated the sample, and was built so that it is close of \( \theta \) in some sense.

There are several techniques to propose an estimator of a parameter \( \theta \). For example, recall that the law of large numbers implies that we can propose \( \bar{X}_n = \frac{1}{n} \sum_{i=1}^{n} X_i \) as an estimator of the theoretical expectation \( \mu = \mathbb{E}(X_1) \). Note that the sample \((X_1, \ldots, X_n)\) was generated from a distribution which takes precisely this unknown value \( \mu \) as one of its parameters.

```r
theta <- 7 # Value assumed unknown.
mean(rnorm(10000,mean=theta)) # Use the observed sample \((x_1, \ldots, x_{10000})\).
[1] 7.019249
```

Following the same idea based on the law of large numbers, we can propose \( \bar{X}_n^2 - (\bar{X}_n)^2 = \frac{1}{n} \sum_{i=1}^{n} X_i^2 - \left( \frac{1}{n} \sum_{i=1}^{n} X_i \right)^2 \) as an estimator of the (assumed unknown) parameter \( \sigma^2 = \mathbb{Var}(X_1) = \mathbb{E}(X_1^2) - [\mathbb{E}(X_1)]^2 \). To estimate \( \sigma^2 \), we thus only used an observed sample of random variables (which follow a distribution depending on the unknown parameter \( \sigma \)).

```r
theta <- 2 # \Var(X_1), assumed unknown.
vecx <- rnorm(10000,sd=sqrt(theta))
mean(vecx^2)-(mean(vecx))^2 # We only used the observed sample.
[1] 1.976646
```

This estimator is biased (see Section 10.4.4). An unbiased estimator of \( \sigma^2 \) is \( \hat{\sigma}^2 = \frac{1}{n-1} \sum_{i=1}^{n} \left( X_i - \bar{X}_n \right)^2 \).

```r
theta <- 2 # \Var(X_1), assumed unknown.
vecx <- rnorm(10000,sd=sqrt(theta))
mean(vecx^2)-(mean(vecx))^2 # We only used the observed sample.
[1] 1.976646
```

Note that this approach can be used to compute integrals. Indeed, for example,

\[
\int_{a}^{b} g(x)dx = \int_{\mathbb{R}} g(x) \mathbb{I}_{[a,b]}(x)dx = \mathbb{E}[g(X)],
\]

where \( X \) is a random variable distributed along the uniform distribution \( \mathcal{U}(a,b) \) over the interval \([a,b]\).
It thus suffices to generate a sample \((x_1, \ldots, x_n)\), with large size \(n\), from random variables following a distribution \(U(a, b)\), to estimate \(E[g(X)]\) with
\[
\frac{1}{n} \sum_{i=1}^{n} g(x_i).
\]
This is called integral computation by \textbf{Monte Carlo simulation}.

\subsection*{10.4.2 Empirical cumulative distribution function}

A random variable following a Bernoulli distribution with parameter \(p\) is defined as a generator to create only 1’s and 0’s, with probability \(p\) of creating a 1, and \(1 - p\) of creating a 0. Given a sample \((x_1, \ldots, x_n)\) of \(n\) realizations of random variables following this distribution, we can then compute the proportion \(\hat{p}\) of values equal to 1 amongst all the values of the sample. This proportion is also equal to the mean \(\bar{x}_n = \frac{1}{n} \sum_{i=1}^{n} x_i\).

By the law of large numbers, as \(n\) gets larger, this mean gets closer to the expectation of \(X\), i.e. \(\mathbb{E}(X) = 1 \times P[X = 1] + 0 \times P[X = 0] = P[X = 1] = p\). This is called the \textbf{frequentist approach of probability}, which stipulates that the probability of an event is defined as the limit of the frequency that this event occurred. We note \(\hat{p}\) the estimator of the proportion \(p\).

Let \(X\) be a random variable and \(x\) a real value (here, \(x\) is not a realization of \(X\)). We can then create a new random variable \(\mathbb{I}[X \leq x]\) which takes the values 1 or 0 depending on whether \(X\) takes values lower or greater than \(x\). Following the same idea, and using a sample \(X_n = (X_1, \ldots, X_n)^\top\), we can create the random variable \(\hat{F}_n(x) := \hat{F}_{X_n}(x) := \frac{1}{n} \sum_{i=1}^{n} \mathbb{I}[X_i \leq x]\). The law of large numbers states that
\[
\frac{1}{n} \sum_{i=1}^{n} \mathbb{I}[X_i \leq x] \xrightarrow{P} \mathbb{E}(\mathbb{I}[X \leq x]).
\]
It can be shown theoretically that \(\mathbb{E}(\mathbb{I}[X \leq x]) = P[X \leq x] = F_{X_1}(x)\). Thus,
\[
\hat{F}_{X_n}(x) \xrightarrow{P} F_{X_1}(x).
\]
The random variable \(\hat{F}_{X_n}(x)\), seen as a function of \(x\), is called the \textbf{empirical cumulative distribution function} of the sample \(X_n = (X_1, \ldots, X_n)\). We shall return to this function when we introduce the bootstrap method in Section 10.6.
The R function `ecdf()` can be used to create simply the empirical cumulative function:

```r
> X <- function() rnorm(1)  # Sample of r.v.s following the distribution \( N(0,1) \).
> vecXn <- function(n) replicate(n,X()) # Sample of r.v.s following the distribution \( N(0,1) \).
> Fnhat <- function(n,x,X) ecdf(X(n))(x) # Creating function \( \hat{F}_n \).
> Fnhat(n=10,x=0,X=vecXn) # First call of \( \hat{F}_n(x) \) with \( x = 0 \).
[1] 0.6
> Fnhat(n=1000,x=0,X=vecXn) # Second call of \( \hat{F}_n(x) \) with \( x = 0 \).
[1] 0.509
```

### 10.4.3 Maximum likelihood estimation

The problem is as follows. We observe in nature some phenomenon and gather data related to this phenomenon. We thus have an observed sample of data \((x_1,\ldots,x_n)\) of size \(n\). We can then assume that these data were created by “Mother Nature”, who generated them with a random variable following a distribution, say \( \mathcal{N}(\theta^*,1) \), for some parameter \( \theta^* \) whose exact value is unknown, but which belongs to the set \([0,1,2,\ldots,9]\).

The aim of the **method of maximum likelihood** is to guess (estimate) the value of \( \theta^* \), based only on the observed sample, which is the only piece of information available about the data generation process (apart from the hypothesis on the distribution of the random variable which generated the data). We are trying to find out which is the most plausible value for \( \theta^* \) (in \([0,1,2,\ldots,9]\)): the one most likely to have led to generating the data we observed.

We shall use a **computer simulation**, which will help us better understand the mechanism of the maximum likelihood method.

To this end, let us pretend for a moment that we are “Mother Nature” (or the “Great Architect”) and choose a value \( \theta^* \) in the set \([0,1,2,\ldots,9]\), called the true value of the parameter \( \theta \). To allow us (“Mother Nature”) to choose a value while allowing us (the “Statistician”) to leave it unknown temporarily, we use the function `runif()`.

```r
> theta.point <- as.integer(runif(1)*10)
> # For now, do not display the value of theta.point.
> n <- 1000
> x1...xn <- rnorm(n,mean=theta.point)
```
We can now shed the clothes of “Mother Nature” and return to our simple statistician’s envelope. We now wish to estimate the unknown $\theta$ with a numerical value, which we note $\hat{\theta}(x_1, \ldots, x_n)$. To this end, we shall use the R optimization function `nlminb()` to create a function $\hat{\theta}(X_1, \ldots, X_n)$ which builds this estimate. It will be built as the value of $\theta$ which maximizes the likelihood $L(\theta; x_1, \ldots, x_n)$ of the sample, or, equivalently, which minimizes $-\log L(\theta; x_1, \ldots, x_n)$. This function is called the maximum likelihood estimator of $\theta$. Note that the likelihood (evaluated at $\theta$) is in a sense a measure of the plausibility of observing the sample if we assume that $\theta^* = \theta$.

We define

```r
> theta.hat <- function(X1...Xn) {
+   start <- 0.5
+   nlminb(start, minus.log.likelihood, X1...Xn=X1...Xn)$par
+ }
```

where the function `minus.log.likelihood()` is defined as

```r
> minus.log.likelihood <- function(theta, X1...Xn) {
+   res <- -sum(log(dnorm(X1...Xn, theta)))
+   return(res)
+ }
```

Now, we can use our estimator on the observations $x_1, \ldots, x_n$ given by “Mother Nature” to get our estimate.

```r
> theta.hat(x1...xn)
[1] 9.024612
```

Since we assumed that the value $\theta^*$ belongs to the set $\{0, 1, \ldots, 9\}$, we can propose as an estimate of $\theta^*$ the value $\hat{\theta} = 9$.

We can now return to the role of “Mother Nature” and check whether the estimate we got is close to the true unknown value $\theta^*$ which we had temporarily hidden.

```r
> theta.point
[1] 9
```

Note that we had assumed here that $\theta^*$ lives in a discrete set (finite or countable), which allowed us to find its exact value with our estimate. This will not be possible with continuous values of parameters to estimate.
### 10.4.4 Sampling variation and properties of an estimator

- **Sampling variation**

  In the practical section, we shall see how to create a tool which simulates the throw of a die. We use it now to throw twenty virtual dice:

  ```r
  > n <- 20
  > res <- throw.die(n)
  > res
  [1] 2 3 4 6 2 6 6 4 1 2 2 5 3 5 3 5 6 3 5
  
  We saw in Section 10.4.2 that we can estimate the probability $p$ of getting a 4 by the proportion of times we got a 4 in the above sample: $\hat{p} = 15.$

  Since a die has six sides, the expected value is $1/6 \approx 0.1667$. This is not quite the value we got. Let us throw twenty other virtual dice to see what is going on.

  ```r
  > res <- throw.die(n)
  > res
  [1] 2 5 3 2 4 1 2 4 4 4 4 4 6 5 1 5 6 2
  
  This time, our estimate of the probability $p$ of getting a 4 is $\hat{p} = 0.4$. The estimate has changed with this new sample. This phenomenon is called **sampling variation**. When we try to estimate an unknown parameter $\theta$, the estimates vary as a function of the samples. Each new observed sample leads to a different estimate of $\theta$.

  If the size of the sample increases (for example $n = 10,000$), there is much less variation between two throws of 10,000 dice.

  ```r
  > n <- 10000
  > res <- throw.die(n)
  > sum(res==4)/n
  [1] 0.1725
  > res <- throw.die(n)
  > sum(res==4)/n
  [1] 0.1678
  ```
Properties of an estimator

How can we know whether an estimator $\hat{\theta}(X_1, \ldots, X_n)$ is accurate enough to estimate an unknown parameter $\theta$? We can define two criteria for an estimator:

- its bias (when estimating $\theta$) $bias = \mathbb{E} [\hat{\theta}(X_1, \ldots, X_n); \theta] = \mathbb{E} [\hat{\theta}(X_1, \ldots, X_n)] - \theta$, which measures whether the estimator is correct “on average”;
- and its variance $var [\hat{\theta}(X_1, \ldots, X_n)]$ which measures the variability of the estimator.

Note that the bias and variance of $\hat{\theta}(X_1, \ldots, X_n)$ depend (theoretically) on $n$.

Now, suppose we have a generator which simulates the behaviour of random variables $X_1, \ldots, X_n$, i.e. we are able to create a large number of samples $(X_1, \ldots, X_n)$ (say $M = 10,000$ or even more, depending on the context). It is then possible, with Monte Carlo simulation, to estimate the bias and variance of an estimator. Indeed, for each observed sample $(x_1, \ldots, x_n)$, we can compute the corresponding estimate $\hat{\theta}(x_1, \ldots, x_n)$. We then have $M$ values $\hat{\theta}_1, \ldots, \hat{\theta}_M$ which can be used to estimate $\mathbb{E} [\hat{\theta}(X_1, \ldots, X_n); \theta]$ with $\hat{\theta} = \frac{1}{M} \sum_{i=1}^{M} \hat{\theta}_i$ and the variance $var [\hat{\theta}(X_1, \ldots, X_n)]$ with $\frac{1}{M} \sum_{i=1}^{M} (\hat{\theta}_i - \hat{\theta})^2$.

In the next example, we use Monte Carlo simulation to estimate the bias and variance of the estimator $\hat{\theta}$ (frequency of 4’s out of $n$ dice throws) of the known parameter $p = \theta = 1/6$. Note that $p$ is the parameter of the random variable $X$ which represents whether we get a 4 when throwing a die. The distribution of $X$ is a Bernoulli with parameter $p = 1/6$.

```r
> n <- 20
> M <- 100000
> vec.theta.hat <- replicate(M, {res <- throw.die(n)
+ theta.hat <- sum(res==4)/n})
> mean(vec.theta.hat)-1/6 # estimate of the bias.
[1] -0.00006716667
> var(vec.theta.hat) # estimate of the variance.
[1] 0.006969351
```

For this example, it can be shown that the random variable $n\hat{\theta}(X_1, \ldots, X_n)$ follows a binomial distribution $Bin(n, p)$, with expectation $np$ and variance $np(1-p)$ (here, $p = 1/6$). Thus the estimator $\hat{\theta}(X_1, \ldots, X_n)$ is an unbiased estimator of $\theta$ and its variance is $\frac{np(1-p)}{n}$.

We can check this numerically:

```r
> p <- 1/6
> p*(1-p)/n
[1] 0.006944444
```
A few techniques to draw from a distribution

Why performing simulations?

- To “check”, using the computer, a mathematical result already known;
- to “demonstrate”, using the computer, a result we can not prove theoretically;
- this can guide us in the demonstration of a difficult mathematical result;
- it is often required when trying to publish results in scientific journals;
- this allows better reasoning as a statistician, as we have already seen in this chapter.

How should one perform efficient simulations? One must:

10.1- properly identify the (heart of) the problem;
10.2- write an outline of an algorithm to solve the problem;
10.3- translate this algorithm into a program written in an interpreted language like R;
10.4- test this program to ensure it works properly;
10.5- translate (possibly) the program using a lower level language (compiled) as C/C++ or Fortran.

Any simulation needs one to be able to simulate random variables from a given law. In the previous sections, we saw how to simulate from a few distributions in R (rnorm(), runif()). When the distribution to simulate from is not implemented in R, you can use one of the methods introduced in this section.

10.5.1 Simulating from another distribution

There sometimes exists a simple formula expressing the random variable $X$ with distribution $L$, from which we wish to sample observations, as a function of one or several random variables with a standard distribution. It is then easy to build a generator with distribution $L$ thanks to this formula. The very simple following example illustrates this point. For example, recall that a random variable following
A better understanding of random variables, distributions and simulations using R specificities

A chi-squared distribution can be obtained by taking the square of a standard normal random variable.

\[ rchi2.1 <- \text{function()} \ rnorm(1)^2 \ # \ X \sim N(0, 1) \Rightarrow X^2 \sim \chi^2_1. \]

**Do it yourself**

Generate observations from a \(TU(2)\) distribution (see the definition of this distribution in Section 10.7), page 408.

### 10.5.2 Inverse transform method

Suppose we know the inverse cumulative distribution function \(F^{-1}_X\) of the random variable \(X\), and we wish to draw observations following the same distribution as \(X\). This is very easy to do with a generator \(U\) with distribution \(U(0, 1)\), thanks to the following formula:

\[ \tilde{X} = F^{-1}_X(U). \]

Indeed, the cumulative distribution function of the random variable \(\tilde{X}\) happens to be \(F_X\). This property is known as inverse transform method and was discovered by R.A. Fisher ([16]).

**Do it yourself**

Recall that the cumulative distribution function of an exponential random variable \(X\) with distribution \(E(\lambda)\) is

\[
F_X(x; \lambda) = \begin{cases} 
1 - e^{-\lambda x}, & x \geq 0, \\
0, & x < 0.
\end{cases}
\]

Calculate \(F^{-1}_X\) then use the function `runif()` to generate observations from the distribution \(E(2)\).

### 10.5.3 Rejection sampling

Suppose we know the density function \(f_X\) of the random variable \(X\), but not its inverse cumulative distribution. We wish to simulate observations following the same
A few techniques to draw from a distribution

Rejection sampling consists in generating data following a distribution with density \( g \) close to \( f \) (in the sense that \( \frac{f_X(x)}{g(x)} \leq c \) for some \( c > 0 \)) and then discard some proportion of these data, so as to get data which follow the desired distribution.

The algorithm is as follows:
1) generate a data point \( y \) using a random variable \( Y \) with density \( g \);
2) generate \( u \) from a random variable \( U \) with density \( U(0, 1) \);
3) if \( c \times g(y) \times u \leq f(y) \), then keep \( y \) as a generated data point; else discard it and return to the start of the algorithm.

The values output by this algorithm can be used as if they were generated by a random variable with density \( f_X \). The best value for the constant \( c \) to minimize the number of rejections is \( c = \sup_x \frac{f_X(x)}{g(x)} \).

Do it yourself

Use the rejection method to generate observations from the distribution \( N(0, 1) \), using as reference function the density of an exponential distribution with parameter \( \lambda = 1 \). Take the value \( c = \sqrt{\frac{e}{1}} \), and use the function \( \text{rbinom()} \) to assign a positive or negative sign to the values given by the rejection algorithm.

10.5.4 Simulation of discrete random variables

Suppose we wish to simulate a sample from a discrete random variable \( X \) which satisfies \( P(X = x_i) = p_i \) for all \( i \) in \( \mathbb{N} \) (or a subset of \( \mathbb{N} \)). Define \( U \) as a random variable with distribution \( U(0, 1) \), which can be sampled from with the function \( \text{runif()} \), and use the following algorithm:

\[
\begin{align*}
X &= x_0 \quad \text{if } 0 < U \leq p_0; \\
X &= x_i \quad \text{if } \sum_{j=0}^{i-1} p_j < U \leq \sum_{j=0}^{i} p_j.
\end{align*}
\]

Do it yourself

Use this algorithm to generate observations from the discrete uniform distribution over the set \{0, 1, 2, 3, 4, 5\}.
Resampling methods, also known as bootstrap methods, consist in using the information available in a sample of observed values ($x_1, \ldots, x_n$) to approximate the distribution of the i.i.d. random variables $X_1, \ldots, X_n$ which generated this sample. We saw in Section 10.2.3.1 that the distribution of a random variable can be described by the cumulative distribution function $F_X$, and we saw in Section 10.4.2 how the cumulative distribution function can be approximated with the empirical cumulative distribution function $\hat{F}_X$. The idea behind bootstrap is to generate several observed data sets $x^*_1 = (x^*_1, \ldots, x^*_n), \ldots, x^*_B = (x^*_{1B}, \ldots, x^*_n)$ following the distribution described by $\hat{F}_X$ (which we know), as a proxy for $F_X$ (which is unknown in practice). We then consider that these new data which can be generated have the same properties as observations we would get if we could use the generator based on $F_X$ (which we cannot in practice). We can then use Monte Carlo techniques, as introduced in Section 10.4.1, to estimate for example the bias and the variance of the estimator $\hat{\theta}(X_1, \ldots, X_n)$ of some unknown parameter $\theta$, with the formulae

\[
\frac{1}{B} \sum_{b=1}^{B} \hat{\theta}(x^*_1, \ldots, x^*_n) - \hat{\theta}(x_1, \ldots, x_n)
\]

\[
\frac{1}{B} \sum_{b=1}^{B} \left( \hat{\theta}(x^*_1, \ldots, x^*_n) - \frac{1}{B} \sum_{b=1}^{B} \hat{\theta}(x^*_1, \ldots, x^*_n) \right)^2.
\]

One question still needs to be answered: how do we generate observations from $\hat{F}_X$? This is in fact very simple: all we need to do is draw with replacement from $F_X$. The bootstrap procedure consists in generating $B$ such samples $x^*_b$ and use them as illustrated in the above example. The R function `sample()` is used for the draw with replacement operation.

We return to the example from Section 10.4.4, where we tried to estimate the bias and variance of the estimator $\hat{\theta}(X_1, \ldots, X_n)$ of some unknown parameter $\theta$, with the formulae

\[
\frac{1}{B} \sum_{b=1}^{B} \hat{\theta}(x^*_1, \ldots, x^*_n) - \hat{\theta}(x_1, \ldots, x_n)
\]

\[
\frac{1}{B} \sum_{b=1}^{B} \left( \hat{\theta}(x^*_1, \ldots, x^*_n) - \frac{1}{B} \sum_{b=1}^{B} \hat{\theta}(x^*_1, \ldots, x^*_n) \right)^2.
\]

In this very simple case, theory states that the bias is zero and the variance is $p(1-p)/n = 0.00694$. 

```r
> n <- 20 ; xvec <- throw.die(n) ; sum(xvec==4)/n
[1] 0.15

Draw with replacement a sample of length $n$ from xvec:

> sample(xvec,n,replace=TRUE)
[1] 6 6 4 5 6 2 5 2 5 4 6 6 5 6 2 1 4

B <- 10000
> vec.theta.star <- replicate(B,sum(sample(xvec,n,replace=TRUE)==4)/n)
> mean(vec.theta.star) - sum(xvec==4)/n
[1] 0.00009
> ((B-1)/B)*var(vec.theta.star) ; sd(vec.theta.star)
[1] 0.006377992
[1] 0.07986632
```

```r
> n <- 20 ; xvec <- throw.die(n) ; sum(xvec==4)/n
[1] 0.15

Draw with replacement a sample of length $n$ from xvec:

```
10.7 Standard and less standard distributions

10.7.1 Standard distributions

Standard probability distributions are implemented in R. In Tables 10.1 and 10.2, we give the functions to compute the density (or mass probability function), the cumulative distribution function and the quantile function of these distributions. We also give the instruction to generate pseudo-random numbers from these distributions.

Table 10.1: Standard discrete distributions. R functions for the mass function (d--), cumulative distribution function (p--), and quantile function (q--). Instruction to generate (r--) pseudo-random numbers from these distributions.

10.7 Standard and less standard distributions

10.7.2† Less standard distributions

In the next tables, we give formulae to generate a sample from a few less standard distributions.

Table 10.3 presents the following distributions: Rademacher Rad, Irwin—Hall Irw(n), Kumaraswamy Kum(a, b), inverse normal GI(µ, λ), Lévy Levy(c), Log-logistic Log-Logis(α, β), Rayleigh Ray(σ²), Rice Rice(σ, ν), multinomial M(n, p₁, ..., pₖ).

SECTION 10.8

Modelling a phenomenon

Suppose we observe the following n = 500 values produced by some phenomenon.

```
> xvec
[1] 1 1 1 2 0 2 0 1 1 1 1 2 1 0 1 1 1 0 1 1 1 2 1 2 1 1 1 2 1 2 2 1 2 1 2 2 1 2
[30] 1 1 0 0 3 2 2 2 1 1 1 0 0 2 1 0 2 1 0 1 2 0 1 2 3 1 1 1 2 1 2 2 1 2 1 1 1
[59] 1 1 0 0 1 1 1 2 1 1 0 0 1 2 1 0 1 1 3 1 0 2 1 0 1 0 2 1 0 1 0 2 1
[88] 1 1 0 0 1 1 1 1 2 2 1 2 1 2 2 1 2 0 1 0 1 3 2 3 1 2 1 2 1 2 0 1 2 3
[117] 1 2 1 2 0 1 1 1 0 2 1 2 3 2 0 2 0 1 1 2 2 0 1 2 0 0 0 3 0
[146] 2 1 1 1 1 0 3 2 0 0 1 0 0 1 3 0 1 2 1 1 1 2 1 2 3 2 1 1 2 1 2 2 2
[175] 4 1 0 1 1 1 1 0 1 1 1 1 1 2 2 0 0 0 0 1 2 1 1 1 2 2 0 1 2 0
[204] 2 0 2 4 1 2 2 2 2 1 0 2 2 1 2 0 0 2 2 2 1 0 1 2 2 1 1 1
```
Given these data, a statistician will try to describe (mathematically) the generative process which led to these values. The observed values seem to arise in an unpredictable fashion, and it seems difficult to find a logical (and deterministic) sequence which would explain them. But can they be described?

Inductive inductive Inferential statistics can be used to go from observed facts about the sample to the probability distribution in the population. To this end, a statistician will (for example) first assume that each of these observations is a realization of a single random variable \( X \) and that these observations are produced independently of one another. Mathematically, this can be stated as “Let \( x_\text{n} = (x_1, \ldots, x_n) \) be an (observed) sample of the random vector \( X = (X_1, \ldots, X_n) \) made of \( n = 500 \) independently and identically distributed (i.i.d.) random variables”. The statistician is thus assuming that “Mother Nature” owns a random number generator \( X \), known to her alone, and that the statistician obviously does not know. The statistician’s aim is to guess what the generator is, as far as possible. This process is called statistical modelling.

The statistician then searches within its toolbox of models and starts with the model which seems most simple (parsimony principle) and adequate. The random variables at play are discrete, so he has the following probabilist models at its disposal:

- the Binomial distribution \( \text{Bin}(m, \alpha) \);
- the Poisson distribution \( \mathcal{P}(\lambda) \);
- and so on.

Given the observations (numbers between 0 and 4), the binomial distribution is most appropriate.

The statistician now needs to estimate the unknown parameters of this model, i.e. plausible values for the parameters of the chosen distribution (here, \( m \) and \( \alpha \)). This is the parameter estimation phase, which was described in Section 10.4.1.
As you may have guessed, the 500 data above were simulated with a computer. We let ourselves on the other side of the fence (the side of “Mother Nature”) to generate these data. We can now reveal that we used the following generator:

\[
X \leftarrow \text{function()} \ \text{rbinom}(500,5,1/4)
\]

One of the main advantages of computers is that we can be simultaneously on either side of the fence, to better understand the phenomena around us. This is of course not possible when working with real data.

The many distributions we have introduced in this chapter can be used to model other types of phenomena. The reader should be able to find a distribution among those we have listed to model a specific phenomenon.

For example, the following remarks are worth noting:

- the Bernoulli distribution (\text{rbinom}(n,1,p)) is used when a random experiment has only two possible outcomes: success, with probability \(p\), and failure with probability \(1 - p\);
- the negative binomial(\(k, p\)) distribution (\text{rbnbinom}(n,k,p)) models the number of observations until the \(k\)-th success (included);
- the Poisson(\(\lambda\)) distribution (\text{rpois}(n,\lambda)) is the distribution of a variable \(X\) which counts the number of realizations of a rare event, for example per unit of time or per unit of area;
- the exponential(\(\lambda\)) distribution (\text{rexp}(n,\lambda)) is used to model the time at which a system breaks down or, equivalently, the lifespan of a system;
- the Pareto distribution is often used to describe the distribution of incomes;
- the Cauchy distribution describes the points of impact of particles emitted in a beam;
- the beta distribution is used to fit distributions with known support.

It is also worth noting that the website http://en.wikipedia.org/wiki/List_of_probability_distributions describes many other distributions.
Warning

We only modeled phenomena involving several independent copies of the same random variable. In Chapter 12, we will present a statistical tool to model some phenomena involving several interacting random variables.
A better understanding of random variables, distributions and simulations using R specificities

**Memorandum**

d--: mass or density function (e.g.: dnorm())
p--: cumulative distribution function (e.g.: pchisq())
q--: quantile function (e.g.: qt(), qf())
r--: pseudorandom number generation (e.g.: runif())

**Exercises**

10.1- Which R function would you use to generate numbers from a \( N(0, 1) \) distribution?

10.2- Which R function would you use to generate numbers from a \( N(2, 10) \) distribution?

10.3- Which R function would you use to calculate the quantiles of a \( \chi^2 \) distribution?

10.4- Which R function would you use to calculate the density of a Fisher distribution?

10.5- Which R function would you use to calculate the quantiles of a Student distribution?

10.6- How would you compute the probability that \( X \) lays between 3 and 5 given that \( X \sim N(4, 2) \)?

10.7- How would you calculate the quantile of order \( p = 0.95 \) of a \( N(0, 1) \)?

**Worksheet**

Simulations

A- Study of the distribution \( f(x) = \frac{2}{\pi} \sqrt{x} \) on \([0, 1]\)

10.1- Check that \( f(x) \) is a density, using the function integrate().

10.2- Simulate a sample of size 1,000 from the distribution defined by the density \( f(x) = \frac{2}{\pi} \sqrt{x} \) over \([0, 1]\).

10.3- Calculate the empirical mean and variance.

10.4- Compare with the theoretical values.

10.5- Calculate and compare the theoretical and empirical probabilities of the following classes:
\([0, 0.30], [0.30, 0.50], [0.50, 0.70], [0.70, 0.85], [0.85, 1]\).
10.8 Modelling a phenomenon

B- Study of the generalized Pareto distribution

Let \( X \) be a random variable following a generalized Pareto distribution \( GP(\mu, \sigma, \xi) \). The density of this distribution is

\[
    f_X(x) = \frac{1}{\sigma} \left( 1 + \frac{\xi(x - \mu)}{\sigma} \right)^{-\frac{1}{\xi} - 1}
\]

with

\[ x \geq \mu \text{ if } \xi \geq 0 \quad \text{and} \quad x \leq \mu - \sigma / \xi \text{ if } \xi < 0. \]

It is given that

\[ \mathbb{E}(X) = \mu + \frac{\sigma}{1 - \xi} \quad (\xi < 1) \]

and

\[ \text{Var}(X) = \frac{\sigma^2}{(1 - \xi)^2(1 - 2\xi)} \quad (\xi < 1/2). \]

We can simulate from \( X \) with the following formula:

\[ X = \mu + \frac{\sigma(U - \xi) - 1}{\xi} \]

where \( U \) is a uniform random variable over \([0, 1]\).

10.1- Propose an \( \text{R} \) code to generate a sample of size \( n \) from a \( GP(\mu, \sigma, \xi) \) distribution. Your source code should use the following variables: \( n, \mu, \sigma \) and \( \xi \).

10.2- Simulate a sample of size \( n = 1,000 \) from the distribution \( GP(0, 1, 1/4) \).

10.3- Calculate the empirical mean and variance.

10.4- Compare with the theoretical values.

10.5- Repeat questions 2 to 3 with \( n = 10,000 \).

10.6- Plot in red the density histogram of your sample. Take 500 equidistant classes and limit the display of the histogram to the interval \([0, 10]\) on the x-axis.

10.7- Overlay the density plot of the \( GP(0, 1, 1/4) \) distribution (in blue). Note that the plot is close to the histogram.

C- Uniform distribution on a square

10.1- Simulate 1,000 observations from \((X_1, X_2)\) which follow the uniform distribution over the square \([0, 1] \times [0, 1]\).

10.2- Get an approximation of the probability that the distance between \((X_1, X_2)\) and the nearest edge is less than 0.25.

10.3- Same question for the distance to the nearest vertex.
10.4- Try to identify the theoretical distribution of the variable distance to the nearest edge: expected value, variance, density.

D- Towards modelling

A statistician believes that the world around us and the phenomena that occur are a large entanglement of random events, which can be modelled in a simplified way by random variables.

10.1- Start with the simple, and classical, example, of a coin toss. The outcome of this experiment is the observation of HEAD or TAIL at each toss. This can be modelled by a random variable $X$ with distribution a Bernoulli with parameter $1/2$. This experiment can be reproduced with a computer. Create a function $X$ which simulates a coin toss. You can toss your virtual coins a few times.

10.2- We can also propose a modelling of the throw of a die. The outcome of this experiment is the observation of the number on the upper side of the die at each throw. If the die is not weighted, this can be modelled by a random variable $X$ with distribution a discrete uniform over $\{1, 2, 3, 4, 5, 6\}$. This experiment can be reproduced with a computer. Create a function `throw.die()` using the function `sample()`. You can throw your virtual die a few times.

10.3- To simulate the game of Yahtzee, we shall create a function `yahtzee()` which throws five virtual dice. Create this function using the parameters `size` and `replace` of the function `sample()`.

10.4- Estimate the probability of getting a yahtzee, i.e. five identical dice in one throw (hint: use the functions `apply()`, `replicate()` and `unique()`). You should get a value close to $1/6^5$.

E- Box-Muller theorem

Let $U_1$ and $U_2$ be two independent random variables uniform over the interval $[0, 1]$. The variables

$$Z_1 = \sqrt{-2 \log(U_1)} \cos(2\pi U_2)$$
$$Z_2 = \sqrt{-2 \log(U_1)} \sin(2\pi U_2)$$

are then two independent standard normal random variables.

10.1- Generate $n = 1,000$ pairs of observations $(z_1, z_2)_1, \ldots, (z_1, z_2)_n$ using this algorithm.

10.2- Use the function `kde2d()` from package `MASS` to estimate the bivariate density of these data.

10.3- Use the functions `spheres3d()` and `surface3d()` from the package `rgl` to plot these observations and the surface of the estimated bivariate density of these data. Also plot the surface of the density of a bivariate standard normal distribution. Note that you get a bell plot, typical of the bivariate normal.
Chapter 11
Confidence intervals and hypothesis testing

Goals of this chapter
This chapter is a catalogue of R functions commonly used to get confidence intervals for usual parameters: mean, proportion, variance, median and correlation. We also present a catalogue of R functions to perform standard hypothesis testing. Furthermore, a few practical worksheets will help the reader understand how to interpret confidence intervals, as well as the various errors related to hypothesis testing.

SECTION 11.1
Notations

Table 11.1 gives the notation we need to define the confidence intervals and hypothesis tests we introduce later in the chapter. Table 11.2 gives the notation of quantiles we shall use.

SECTION 11.2

Confidence intervals

We are given a sample $X_n = (X_1, \ldots, X_n)^T$ of random variables which depend on an unknown parameter $\theta$ which we wish to estimate. A random confidence interval with level (of confidence) $1 - \alpha$ for $\theta$ consists in two random variables $A := a(X_n; \alpha)$ and $B := b(X_n; \alpha)$ such that

$$P[A \leq \theta \leq B] = 1 - \alpha.$$  

The random variables $A$ and $B$ are the boundaries of this random confidence interval, usually noted

$$CI_{1-\alpha}(\theta) = [A, B].$$

When the sample is observed and we are given the data $(x_1, \ldots, x_n)$, we note

$$ci_{1-\alpha}(\theta) = [a, b]$$

the resulting realization of the confidence interval, where $a = a(x_1, \ldots, x_n; \alpha)$ and $b = b(x_1, \ldots, x_n; \alpha)$. In the remainder of this chapter, by abuse of language, we shall not distinguish between a random confidence interval and its realization.

Finally, note that the correct way of interpreting a (random or realized) confidence interval will be given in the practical section. For now, we only give a catalogue of classical confidence intervals for the usual parameters: mean, proportion, variance, median and correlation.

11.2.1 Confidence intervals for the mean

- Case of a large sample ($n > 30$) or of a small sample under the assumption of normality
  - **Definition:** A confidence interval at level $(1 - \alpha)$ for the mean $\mu$ is:
11.2 Confidence intervals

\[ c_{1-\alpha} (\mu) = \left[ \bar{x} - t_{1-\alpha/2} \frac{\hat{\sigma}}{\sqrt{n}}, \bar{x} + t_{1-\alpha/2} \frac{\hat{\sigma}}{\sqrt{n}} \right]. \]

**R instruction:** The confidence interval is given by the function `t.test()`.

**Example of use:** Using the nutrition study, we wish to build a confidence interval of the mean of the weight of elderly people living in Bordeaux.

```r
> t.test(weight, conf.level=0.9)$conf.int
[1] 65.16024 67.80436
attr(, "conf.level")
[1] 0.9
```

We get the confidence interval [65.16, 67.80] with confidence level 0.9.

- **Case of small samples**

**Definition:** When no assumption is made about the data, we suggest using a bootstrap approach. Several bootstrap confidence intervals are given in [14].

**R instruction:** The functions `boot()` and `boot.ci()` from package `boot` can be used.

**Example of use:** We are given a sample of cholesterol levels (in g/l) of ten women. This sample is representative of women living in France:

```r
> chol.levels <- c(3,1.8,2.5,2.1,2.7,1.9,1.5,1.7,2,1.6)
Without the assumption of normality, we propose a confidence interval at the 95% level of the mean cholesterol level of women living in France.
```

```r
> require(boot)
> mymean <- function(x, indices) mean(x[indices])
> level.boot <- boot(chol.levels, mymean, R = 999, stype = "i", + sim = "ordinary")
> boot.ci(level.boot, conf = 0.95, type = c("norm", "basic”, + "perc", "bca"))
```

**BOOTSTRAP CONFIDENCE INTERVAL CALCULATIONS**

Based on 999 bootstrap replicates

```r
CALL:
boot.ci(boot.out = chol.levels.boot, conf = 0.95, type = + c(“norm”, “basic”, “perc”, “bca”))
```

**Intervals:**

<table>

</tr>
</tbody>
</table>

Calculations and Intervals on Original Scale
11.2.2 Confidence intervals for a proportion $p$

- Case of large samples ($np \geq 5$ and $n(1 - p) \geq 5$)

  - **Definition:** A confidence level at level $(1 - \alpha)$ for the unknown proportion $p$ is:

    $$
ic_{1-\alpha}(p) = \left[ \hat{p} - u_{1-\alpha/2} \sqrt{\frac{\hat{p}(1 - \hat{p})}{n}}, \hat{p} + u_{1-\alpha/2} \sqrt{\frac{\hat{p}(1 - \hat{p})}{n}} \right].$$

  - **Conditions for validity:** The required conditions ($np \geq 5$ and $n(1 - p) \geq 5$) can be "checked" *a posteriori* by replacing $p$ with the boundaries of the confidence interval. If the conditions are not verified, use the exact method given for the case of small samples.

  - **R instruction:** The function `binom.approx()` from package `epitools` can be used.

  - **Example of use:** We wish to build a confidence interval for the proportion of men (coded 2 below) amongst elderly people in Bordeaux, from the nutrition study.

    ```r
    require(epitools)
    table(gender) # Sampling distribution of the gender variable.
    gender
    1 2
    85 141
    > binom.approx(141,226)[c("lower","upper")]
      # Calculating the CI with n=226.
      lower upper
      1 0.5607393 0.6870483
    ```

    The function `prop.test()` also gives a confidence interval for the proportion, based on the score statistic.

- Case of small samples: exact calculation

  - **Definition:** A confidence interval at level $(1 - \alpha)$ for proportion $p$ comes from

    $$n\hat{p} \sim \text{Bin}(n, p).$$

  - **R instruction:** You can use the function `binom.test()`.
11.2 Confidence intervals

Example of use: We return to the previous example to compute exactly the confidence interval for the proportion of men amongst elderly people in Bordeaux.

```r
> binom.test(141,226)$conf # Computing the CI with n=226.
[1] 0.5572321 0.6872590
attr(, "conf.level")
[1] 0.95
```

Tip

The function `binom.exact()` from the package `epitools` returns the same confidence interval.

11.2.3 Confidence intervals for a variance

- Case of samples under the assumption of normality

  Definition: A confidence interval at level \((1 - \alpha)\) for the variance \(\sigma^2\) is:

  \[
  ic_{1-\alpha}(\sigma^2) = \left[ \frac{(n - 1)\hat{\sigma}^2}{q_{\alpha/2}^{n-1}}, \frac{(n - 1)\hat{\sigma}^2}{q_{1-\alpha/2}^{n-1}} \right].
  \]

  R instruction: The relevant function is `sigma2.test()`. This function is included in the package associated with this book.

  Example of use: We wish to build a confidence interval for the variance of the weight of elderly people living in Bordeaux, using the nutrition study.

  ```r
  > sigma2.test(weight,conf.level=0.9)$conf
  [1] 124.8330 170.3277
  attr(, "conf.level")
  [1] 0.9
  ```

- Case of samples without the assumption of normality

When no assumption is made about the data, we suggest using a bootstrap method, as for the mean.

R instruction: You can use the functions `boot()` and `boot.ci()` available in package `boot`. 
Example of use: We return to the data about women’s cholesterol levels and compute a confidence interval for the cholesterol level without assuming normality of the data.

```r
> chol.levels <- c(3, 1.8, 2.5, 2.1, 2.7, 1.9, 1.5, 1.7, 2, 1.6)
> require(boot)  # Load package boot.
> variance <- function(x, indices) var(x[indices])
> level.boot <- boot(chol.levels, variance, R=999,
>                     type="i", sim="ordinary")
> boot.ci(level.boot, conf=0.95, type=c("norm",
>                                         "basic", "perc", "bca"))
BOOTSTRAP CONFIDENCE INTERVAL CALCULATIONS
Based on 999 bootstrap replicates
CALL: boot.ci(boot.out=level.boot, conf=0.95, type=c("norm",
         "basic", "perc", "bca"))
Intervals:
Level       Normal        Basic
95%  ( 0.1060, 0.4412 ) ( 0.1026, 0.4448 )
Level       Percentile   BCA
95%  ( 0.0521, 0.3943 ) ( 0.1201, 0.4670 )
Calculations and Intervals on Original Scale
Some BCa intervals may be unstable
```

Note: Note that for large samples where you cannot assume normality, you can use an asymptotic approach. This is available in the package asympTest. Here is an example computing a confidence interval for the weight of elderly people living in Bordeaux using the nutrition study.

```r
> require(asympTest)
> asymp.test(weight, par="var")$conf
[1] 121.6842 167.3158
attr(, "conf.level")
[1] 0.95
```

### 11.2.4 Confidence intervals for a median

**Definition:** A confidence interval at level $(1 - \alpha)$ for the median $m_e$ is:

$$ic_{1-\alpha}(m_e) = [x_{(m_1)}; x_{(m_2+1)}]$$

where the $x_{(i)}$ are the ordered values of the sample of size $n$, $m_1$ is the smallest value such that $P(L \leq m_1) \geq \alpha/2$, and $m_2$ is the largest value such that $P(L \geq m_2) > \alpha/2$ with $L \sim Bin(n, 0.5)$. 
11.2 Confidence intervals

- **R instruction:** A confidence interval for the median can be computed with the function `qbinom()`.

- **Example of use:** We return to the example of cholesterol levels and wish to build a 95% confidence interval for the median cholesterol level of women living in France.

```r
chol.levels <- c(3.1, 1.8, 2.5, 2.1, 2.7, 1.9, 1.5, 1.7, 2.1, 1.6)
m1 <- qbinom(0.025, length(chol.levels), 0.5)
m2 <- qbinom(1-0.025, length(chol.levels), 0.5)
median.ci <- c(sort(chol.levels)[m1], sort(chol.levels[m2+1]))
median.ci
[1] 1.6 2.0
```

Note

It is always possible to build a bootstrap confidence interval. For this example, the percentile method returns:

```r
chol.levels <- c(3.1, 1.8, 2.5, 2.1, 2.7, 1.9, 1.5, 1.7, 2.1, 1.6)
require(boot)
mymedian <- function(x,indices) median(x[indices])
levels.boot <- boot(chol.levels, mymedian, R=999,
+ stype="i", sim="ordinary")
levels.int <- boot.ci(levels.boot, conf=0.95, type="perc")
levels.int$perc[4:5]
[1] 1.7 2.6
```

Also note that a non-parametric confidence interval is implemented in the function `wilcox.test()`.

```r
wilcox.test(chol.levels, conf.int=TRUE)$conf
[1] 1.7 2.45
attr(,"conf.level")
[1] 0.95
```

11.2.5 Confidence intervals for a correlation coefficient

- **Definition:** A confidence interval at level \((1 - \alpha)\) for the correlation coefficient \(\rho\) is:

\[
\hat{\rho}_{1-\alpha}(\rho) = \left[ \frac{\exp(\hat{\theta}_{1-\alpha}/2) - 1}{\exp(\hat{\theta}_{1-\alpha}/2) + 1}; \frac{\exp(\hat{\theta}_{1+\alpha}/2) - 1}{\exp(\hat{\theta}_{1+\alpha}/2) + 1} \right]
\]

where \(\hat{\theta}_{1-\alpha} = \frac{1}{2} \ln \left( \frac{1 + \hat{\rho}}{1 - \hat{\rho}} \right) - u_{1-\alpha/2} \frac{1}{\sqrt{n-3}}\) and \(\hat{\theta}_{1+\alpha} = \frac{1}{2} \ln \left( \frac{1 + \hat{\rho}}{1 - \hat{\rho}} \right) + u_{1-\alpha/2} \frac{1}{\sqrt{n-3}}\).

- **R instruction:** You can use the function `cor.test()`.
Example of use: We now wish to build a confidence interval for the correlation coefficient between the weight and height of elderly people living in Bordeaux, based on the nutrition study.

```
> cor.test(weight, height)$conf
[1] 0.5450122 0.7032775
attr(, "conf.level")
[1] 0.95
```

This confidence interval is only valid under the assumption of joint normality of the pair of variable, here (weight, height). If this assumption is not verified, you can always use bootstrap.

### 11.2.6 Summary table for confidence intervals

**SECTION 11.3**

### Standard hypothesis testing

We present briefly the philosophy of hypothesis testing.

Hypothesis tests propose a tool to aid decision or to validate an assertion of interest \( \mathcal{H}_1 \) (often called the “alternative hypothesis”). This statistical decision will be made based on a decision rule, which is intuitively built from a test statistic \( T \) (which depends on an observed sample). This decision may be wrong, so it is important to measure the risk of accepting \( \mathcal{H}_1 \) for each of the situations which are described by not-\( \mathcal{H}_1 \). These risks of wrongly accepting \( \mathcal{H}_1 \) are called risks of the first kind and are defined under not-\( \mathcal{H}_1 \). We then aim at controlling the worse (largest) of these risks, which is defined for a specific situation of not-\( \mathcal{H}_1 \), usually noted \( \mathcal{H}_0 \).
and called the “null hypothesis”. Thus any decision rule is associated with a maximum risk. Amongst potential decision rules, we choose the one which guarantees a low maximum risk \( \alpha \), specified in advance (usually 5\%). This is called the **level of significance** \( \alpha \) of the test.

When we apply this decision rule to an observed data set, it is interesting to know what is the smallest significance level that would have led to accepting \( H_1 \). In both cases, the answer is what is called the \( p \)-value, defined as the (maximal) risk level that would lead to accepting \( H_1 \). The \( p \)-value is given by any statistical software, and the user can then compare this risk to a significance level \( \alpha \) (fixed by the user or by some custom). Its interpretation is extremely simple: the smaller the \( p \)-value, the more reliable the decision (to accept the assertion of interest \( H_1 \)).

In the same context, it is worth mentioning the concept of **power of a test**: this function measures the probability of accepting \( H_1 \) under any situation. These concepts will be explained and detailed, using the power of \( R \), in the practical section.

The remainder of this section gives a catalogue of classical statistical testing procedures and of \( R \) instructions to put them to use. Unless specified otherwise, the significance level of all tests presented hereafter is fixed at \( \alpha = 5\% \).

Although we prefer our approach of hypothesis testing, which insists on the assertion of interest \( H_1 \), we present a mathematical curiosity which explains why some authors (often mathematicians) use the notation \( H_0 \) to designate not-\( H_1 \). This makes sense from a mathematical point of view, since the logic of hypothesis testing is similar to proof by contradiction. Consider the simplistic example where we wish to prove \( H_1 : \mu_X > \mu_0 \) based on a sample \( X_n = (X_1, \ldots, X_n) \) of i.i.d. r.v.s following the distribution \( N(\mu_X, 1) \).

1. We reason by contradiction and suppose our hypothesis \( H_1 \) is wrong. We are then in the contrary of \( H_1 \), which is noted here \( H_0 : \mu_X \leq \mu_0 \). For example, this corresponds to the situation where \( \mu_X = \tilde{\mu} \) for some value \( \tilde{\mu} \) lesser than or equal to \( \mu_0 \).
2. We then wish to measure the plausibility of the contradiction hypothesis \( H_0 \). To this end, we shall measure how negative is the unknown spread \( d = \mu_X - \mu_0 \), estimated by the test statistic \( T = \bar{X}_n - \mu_0 = \bar{X} + (\tilde{\mu} - \mu_0) \), where \( \bar{X} \sim N(0, 1/n) \).
3. The data, which carry information about the value of \( \mu_X \) since they were generated from a distribution with this expectation, give a realization \( t_{obs} \) of the statistic \( T \). If \( H_0 \) were true, then the random variable \( T = \bar{X}_n - \mu_0 \), which measures the spread between \( \mu_X \) and \( \mu_0 \), would be unlikely to produce large values. Thus:
\( p(\tilde{\mu}) := P_{\tilde{\mu}=\mu_0}[T \geq t_{obs}] \)

\[= P_{\tilde{\mu}=\mu_0}[\tilde{T} + \tilde{\mu} - \mu_0 \geq t_{obs}] \]

\[= P_{\tilde{\mu}=\mu_0}[\tilde{T} \geq t_{obs} - (\tilde{\mu} - \mu_0)] \quad \text{from (1)} \]

\[\leq P_{\tilde{\mu}=\mu_0}[\tilde{T} \geq t_{obs}] := \tilde{p} \]

(independent from \( \tilde{\mu} \) here).

Note that \( p(\tilde{\mu}) \) (of which we do not know the numerical value) can be seen as an extension of the \( p \)-value for the situation \( \tilde{\mu} \) and that \( \tilde{p} \) is only a computable upper bound, used to control this extended \( p \)-value. If the value \( \tilde{p} = P[N(0, 1/n) > t_{obs}] \) is very small (and thus the probability \( p(\tilde{\mu}) \) is even smaller), we get a (quasi) contradiction since the event \( \{T \geq t_{obs}\} \) with probability \( p(\tilde{\mu}) \) did occur, even though we expected it to almost never happen under \( H_0 \). By contradiction, our hypothesis \( H_1 \) is certainly true and \( \tilde{p} \) (smallest upper bound of the \( p(\tilde{\mu}), \tilde{\mu} \leq \mu_0 \), attained when \( \tilde{\mu} = \mu_0 \)) expresses the strength of the contradiction (or of conviction) of not-\( H_1 \), or the risk of being wrong when deciding \( H_1 \). The probability \( \tilde{p} \) is nothing else than the \( p \)-value we defined earlier.

### 11.3.1 Parametric tests

#### 11.3.1.1 Tests of the mean

- Comparing the theoretical mean and a reference value (case with one sample)

  - **Description of the test**: Let \( X \) be a quantitative variable with theoretical mean \( \mu \) and variance \( \sigma^2 \). Using a sample of size \( n \), we wish to compare the theoretical mean \( \mu \) to a reference value \( \mu_0 \). The hypotheses of the test are \( H_0 : \mu = \mu_0 \) and \( H_1 : \mu \neq \mu_0 \). Under \( H_0 \), the test statistic is:

    \[ T = \sqrt{n} \left( \frac{\bar{X} - \mu_0}{\tilde{\sigma}} \right) \sim t(n-1). \]

  - **Conditions for validity**: Normally distributed data or large sample size \( (n > 30) \).
11.3 Standard hypothesis testing

▶ **R instruction:** Use the function `t.test()`.

▶ **Example of use:** In the data set `Intima-media`, we wish to know whether people with a Body Mass Index (BMI) above 30 have thicker intima-media on average than the population from which the sample is taken. We make the assumption that the theoretical mean of intima-media thickness in this population is 0.58 mm.

```r
BMI <- weight/((height/100)^2)
measure1 <- measure[BMI>30]
t.test(measure1,mu=0.58,alternative="greater")
```

```
One Sample t-test
data:  measure1
t = 1.5272, df = 8, p-value = 0.08262
alternative hypothesis: true mean is greater than 0.58
95 percent confidence interval:
  0.5715358      Inf
sample estimates:
mean of x
  0.6188889
```

We cannot give a positive answer to the question, at the specified risk level $\alpha = 5\%$.

- **Comparing two theoretical means (case with two samples)**

▶ **Description of the test:** Let $X_1$ and $X_2$ be two quantitative variables (measuring the same quantity, but in two different populations). We assume that $X_1$ has theoretical mean $\mu_1$ and variance $\sigma_1^2$ and that $X_2$ has theoretical mean $\mu_2$ and variance $\sigma_2^2$. Using estimations computed from two samples of respective size $n_1$ and $n_2$ from the two populations, we wish to compare $\mu_1$ and $\mu_2$. The hypotheses of the test are $H_0 : \mu_1 = \mu_2$ and $H_1 : \mu_1 \neq \mu_2$. Under $H_0$, the test statistic is:

$$T = \frac{\bar{X}_1 - \bar{X}_2}{\hat{\sigma} \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}} \sim T(n_1 + n_2 - 2)$$

where $\hat{\sigma}^2 = \frac{(n_1-1)\hat{\sigma}_1^2 + (n_2-1)\hat{\sigma}_2^2}{n_1+n_2-2}$, $\hat{\sigma}_1$ and $\hat{\sigma}_2$ are estimators of the variance in the two populations.

▶ **Conditions for validity:** Normally distributed variables $X_1$ and $X_2$ and equal variance.

▶ **R instruction:** Use the function `t.test()`.
Example of use: We wish to see whether there is a significant difference of intima-media thickness between women with a physical activity and women with no such activity.

```r
> measure.SPORT.1 <- measure[SPORT==1 & GENDER==2]
> measure.SPORT.0 <- measure[SPORT==0 & GENDER==2]
> t.test(measure.SPORT.1, measure.SPORT.0, var.equal=F)
```

Welch Two Sample t-test
data: measure.SPORT.1 and measure.SPORT.0
t = -1.4693, df = 53.179, p-value = 0.1476
alternative hypothesis: true difference in means is not equal to 0
95 percent confidence interval:
-0.07488130 0.01155649
sample estimates:
mean of x mean of y
0.5130435 0.5447059

We cannot give a positive answer to the question, at the specified risk level \( \alpha = 5\% \).

However, we need to check the hypothesis of equal variances (see the next section). Thus the value of the argument var.equal in the function `t.test()` should be set depending on the result of the test of equal variances. The test statistic is then:

\[
T^* = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}
\]

This statistic follows a Student distribution; the number of degrees of freedom can be computed using Satterthwaite’s approximation. For large samples, the statistic \( T^* \) follows a \( \mathcal{N}(0, 1) \) distribution.

Case of paired samples

Description of the test: We wish to compare the theoretical means of two random variables \( X_1 \) and \( X_2 \) based on two paired samples. To this end, we use the difference random variable \( D = X_1 - X_2 \), and we compare the theoretical mean \( \delta = \mu_1 - \mu_2 \) of \( D \) with the reference value 0. We are thus back to the case of a test of the mean for one sample. The hypotheses of the test are \( \mathcal{H}_0 : \mu_1 - \mu_2 = 0 \) and \( \mathcal{H}_1 : \mu_1 - \mu_2 \neq 0 \). Under \( \mathcal{H}_0 \), the test statistic is:

\[
T = \sqrt{n \frac{\hat{\delta}}{\delta}} \sim t(n-1).
\]
11.3 Standard hypothesis testing

- **Conditions for validity**: Normally distributed data or large sample size \((n > 30)\).

- **R instruction**: Use the function `t.test()` with the argument paired=TRUE.

- **Example of use**: We wish to compare the results from two labs for a specific examination. Both labs made the necessary measurement on fifteen patients.

```r
> dose.lab1 <- c(22,18,28,26,13,8,21,26,27,29,25,24,  
  + 22,28,15)
> dose.lab2 <- c(25,21,31,27,11,10,25,26,29,28,26,23,  
  + 22,25,17)
> t.test(dose.lab1,dose.lab2,paired=TRUE)
```

```
Paired t-test

data: dose.lab1 and dose.lab2
t = -1.7618, df = 14, p-value = 0.0999
alternative hypothesis: true difference in means is not equal to 0
95 percent confidence interval:
-2.0695338 0.2028671
sample estimates:
mean of the differences
-0.9333333
```

At the specified risk level \(\alpha = 5\%\), we cannot decide that the two labs give different results on average.

Note

This test is valid when \(n\) is large or when the data can be assumed to be normally distributed. Otherwise, we advise you to use a non-parametric test such as the sign test or Wilcoxon’s test (see the section on non-parametric tests).

11.3.1.2 Tests of variance

- **Comparing the theoretical variance with a reference value (case with one sample)**

  - **Description of the test**: Let \(\sigma^2\) be the variance of a quantitative variable \(X\) from population \(P\). The hypotheses of the test are \(H_0 : \sigma^2 = \sigma_0^2\) and \(H_1 : \sigma^2 \neq \sigma_0^2\). Under \(H_0\), the test statistic is:

    \[
    T = \frac{(n-1)\hat{\sigma}^2}{\sigma_0^2} \sim \chi^2(n-1).
    \]
**Conditions for validity:** Variable X must follow a normal distribution.

**R instruction:** You can use the function `sigma2.test()` from the package associated with this book.

**Example of use:** A factory makes cans of weight \( \mu \) with precision \( \sigma^2 = 10 \). We wish to show that the production line is faulty (the precision is not \( \sigma^2 = 10 \)). Here are the weights from a series of twenty cans.

```r
> weights <- c(165.1, 171.5, 168.1, 165.6, 166.8, 170.0, 168.8, 171.1, 168.8, 173.6, 163.5, 169.9, 165.4, 174.4, 171.8, 166.0, 174.6, 174.5, 166.4, 173.8)
> sigma2.test(weights, var0=10)
```

```
One-sample Chi-squared test for given variance
data: weights
X-squared = 24.2045, df = 19, p-value = 0.3768
alternative hypothesis: true variance is not equal to 10
95 percent confidence interval:
  7.367682 27.176225
sample estimates:
var of x
12.73924
```

We cannot give a positive answer to the question at the specified risk level \( \alpha = 5\% \).

**Note**

If the data are not normally distributed, and for large samples, you can use the function `asymp.test(x, parameter="var", reference=10)`.

**Comparing two theoretical variances (case with two samples)**

**Description of the test:** This test is often useful as a prerequisite for other tests, such as the comparison of two means in the case with small samples. Indeed, in this case, the statistic is not the same depending on whether the variances of \( X_1 \) (variable for the first sample) and \( X_2 \) (variable for the second sample) can be considered as equal or not. The hypotheses of the test are \( H_0 : \sigma_1^2 = \sigma_2^2 \) and \( H_1 : \sigma_1^2 \neq \sigma_2^2 \). Under \( H_0 \), the test statistic is:

\[
T = \frac{\hat{\sigma}_1^2}{\hat{\sigma}_2^2} \sim F(n_1 - 1, n_2 - 1).
\]

**Conditions for validity:** \( X_1 \) and \( X_2 \) must be normally distributed.
11.3 Standard hypothesis testing

▶ **R instruction:** You can use the function `var.test()`.

▶ **Example of use:** In the data set `INTIMA-MEDIA`, we wish to know whether within the population of women, there is a significant difference of variance of intima-media thickness between women who have a physical activity and those who do not.

```r
> measure.SPORT.1 <- measure[SPORT==1&GENDER==2]
> measure.SPORT.0 <- measure[SPORT==0&GENDER==2]
> var.test(measure.SPORT.1, measure.SPORT.0)
```

```
F test to compare two variances
data: measure.SPORT.1 and measure.SPORT.0
F = 0.303, num df = 22, denom df = 33, p-value = 0.00468
alternative hypothesis: true ratio of variances is not equal to 1
95 percent confidence interval:
0.1431908 0.6815918
sample estimates:
ratio of variances
0.3029910
```

We can conclude that there is a significant difference in the variance of intima-media thickness between women who have a physical activity and those who do not, at the $\alpha = 5\%$ risk level.

**Tip**

Remember to use the function `asymp.test()` for large samples without the assumption of normality.

**See also**

For the comparison of more than two variances, see Bartlett’s test, which will be presented in the section on analysis of variance, page 514.

### 11.3.1.3 Tests of proportion

- **Comparing a theoretical proportion to a reference value (case with one sample)**

  ▶ **Description of the test:** Let $p$ be the unknown frequency of a trait in a given population. We observe data of presence/absence of this trait on individuals in a sample of size $n$ in this population. The hypotheses of the test are: $H_0 : p = p_0$ and $H_1 : p \neq p_0$. Under $H_0$, the test statistic is:
\[ U = \frac{\hat{p} - p_0}{\sqrt{\frac{p_0(1-p_0)}{n}}} \sim N(0, 1). \]

- **Conditions for validity:** The sample must be large enough: check that \( np_0 \geq 5 \) and \( n(1-p_0) \geq 5 \).

- **R instruction:** You can use the function `prop.test()`.

- **Example of use:** Assume (and this really is no more than an assumption) that a case study called “Study of pregnant women in Abidjan” led to data collection after a large campaign of information and prevention of HIV infection, which aimed at reducing the proportion of people infected by HIV, especially amongst people aged 18 to 25. Assume that the first aim is that the prevalence rate for pregnant women aged 18 to 25 be reduced to less than 10%. Using the subsample of pregnant women aged 18 to 25, we therefore wish to know whether the HIV prevalence rate is less than \( p_0 = 0.1 \). The data set is available at the URL [http://www.biostatisticien.eu/springeR/aidsafrica.xls](http://www.biostatisticien.eu/springeR/aidsafrica.xls).

```r
> table(HIV[age<=25])
   0   1
137  10

> prop.test(10,147,0.1,alternative="less",correc=FALSE)
1-sample proportions test without continuity correction
data: 10 out of 147, null probability 0.1
X-squared = 1.6697, df = 1, p-value = 0.09815
alternative hypothesis: true p is less than 0.1
95 percent confidence interval:
 0.0000000 0.1105720
sample estimates:
p 0.06802721
```

We cannot give a positive answer to the question at the specified \( \alpha = 5\% \) risk level.

- **Case of small samples:** In that case, the function `binom.test()` can be used for an exact calculation based on the binomial distribution.

```r
> binom.test(10,147,0.1,alternative="less")

Exact binomial test
data: 10 and 147
number of successes = 10, number of trials = 147,
p-value = 0.1208
alternative hypothesis: true probability of success is less than 0.1
95 percent confidence interval:
 0.0000000 0.1126571
sample estimates:
probability of success 0.06802721
```
11.3 Standard hypothesis testing

Once again, we cannot give a positive answer to the question, at the specified \( \alpha = 5\% \) risk.

- **Comparing two theoretical proportions (case with two samples)**

  ▶ *Description of the test:* Let \( p_1 \) (respectively \( p_2 \)) be the unknown proportion of individuals with a given trait within a population \( \mathcal{P}_1 \) (respectively \( \mathcal{P}_2 \)). We wish to compare \( p_1 \) and \( p_2 \). To this end, we use the frequencies \( \hat{p}_1 \) and \( \hat{p}_2 \) of this trait in two representative samples of the two populations, of respective sizes \( n_1 \) and \( n_2 \). The hypotheses of the test are: \( H_0 : p_1 = p_2 \) and \( H_1 : p_1 \neq p_2 \). Under \( H_0 \), the test statistic is:

\[
U = \frac{\hat{p}_1 - \hat{p}_2}{\sqrt{\frac{\hat{p}(1-\hat{p})}{n_1} + \frac{\hat{p}(1-\hat{p})}{n_2}}} \sim \mathcal{N}(0, 1)
\]

with \( \hat{p} = \frac{n_1 \hat{p}_1 + n_2 \hat{p}_2}{n_1 + n_2} \).

▶ *Conditions for validity:* Large samples: check that \( n_1 \hat{p} \geq 5 \), \( n_1(1-\hat{p}) \geq 5 \), \( n_2 \hat{p} \geq 5 \) and \( n_2(1-\hat{p}) \geq 5 \).

▶ *R instruction:* Use the function `prop.test()`.

▶ *Example of use:* In the therapeutic test “Ditrame”, the underlying question is whether the treatment has an effect on the HIV status of the child. If not, then the HIV status of the child is independent of the treatment followed by the mother. To answer this question, we use the table of crossed variables Mother’s treatment group (TTTGRP) and Child’s HIV status (HIVSTATUS). We give the observed contingency table of these two variables. The data set is available at the URL http://www.biostatisticien.eu/springerR/TME_Africa.xls.

```r
> table(TTTGRP,HIVSTATUS)
HIVSTATUS
TTTGRP 0 1 9
  0 139 59 3
  1 152 41 7
> mytable <- as.matrix(table(TTTGRP,HIVSTATUS)[,c(2,1)])
> prop.test(mytable,correc=FALSE)
2-sample test for equality of proportions without continuity correction
data: mytable
X-squared = 3.7574, df = 1, p-value = 0.05257
alternative hypothesis: two.sided
95 percent confidence interval:
-0.0004122543 0.1715013839
sample estimates:
prop 1 prop 2
0.2979798 0.2124352
```
With a risk of being wrong less than 5%, we can assert that the theoretical proportion \( p_1 \) of children with HIV in the non-treated group is greater than the theoretical proportion \( p_2 \) of children with HIV in the treated group.

### 11.3.1.4 Tests of correlation

- **Comparing a theoretical correlation coefficient with a reference value (case with one sample)**

  - **Description of the test:** Let \( \rho \) be the correlation coefficient of two quantitative variables \( X \) and \( Y \). We wish to test the hypotheses \( \mathcal{H}_0 : \rho = \rho_0 \) and \( \mathcal{H}_1 : \rho \neq \rho_0 \). Under \( \mathcal{H}_0 \), the test statistic is:

    \[
    U = \frac{Z - \mu_Z}{\sigma_Z} \sim \mathcal{N}(0, 1)
    \]

    with \( Z = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right), \mu_Z = \frac{1}{2} \ln \left( \frac{1 + \rho_0}{1 - \rho_0} \right), \sigma^2_Z = \frac{1}{n - 3} \).

    If we are interested in the linear association between \( X \) and \( Y \) (tested by taking \( \rho_0 = 0 \)), then the test statistic under \( \mathcal{H}_0 \) is:

    \[
    T = \frac{\hat{\rho} \sqrt{n - 2}}{\sqrt{1 - \hat{\rho}^2}} \sim T(n - 2).
    \]

  - **Conditions for validity:** The pair \( (X, Y) \) follows a joint normal distribution.

  - **R instruction:** You can use the function `cor.test()` if you are testing the linear association between \( X \) and \( Y \). For a value other than \( \rho_0 = 0 \), you can use the function `cor0.test()` available in the package associated with this book.

  - **Example of use:** In the data set `BMI-child`, we are interested in the linear association between height and weight.

    ```r
    > cor.test(weight, height)
    
    Pearson’s product-moment correlation
    
    data: weight and height
    t = 13.4327, df = 150, p-value < 2.2e-16
    alternative hypothesis: true correlation is not equal to 0
    95 percent confidence interval:
    0.6570527 0.8036174
    sample estimates:
    cor
    0.7389562
    ```
At the 5% risk level, we can assert that there is a linear association between height and weight.

- **Comparing two theoretical correlation coefficients (case with two samples)**
  
  - **Description of the test:** We are given two independent populations. Let $\rho_1$ be the correlation coefficient between $X$ and $Y$ in population 1, and $\rho_2$ the correlation coefficient between $X$ and $Y$ in population 2. We wish to test whether these two correlation coefficients are equal, based on two samples of size $n_1$ and $n_2$. The hypotheses of the test are $H_0 : \rho_1 = \rho_2$ and $H_1 : \rho_1 \neq \rho_2$. Under $H_0$, the test statistic is:
    
    $$U = \frac{Z_1 - Z_2}{\sqrt{1/(n_1 - 3) + 1/(n_2 - 3)}} \sim N(0, 1)$$
    
    with $Z_1 = \frac{1}{2} \ln(\frac{1+\hat{\rho}_1}{1-\hat{\rho}_1})$ and $Z_2 = \frac{1}{2} \ln(\frac{1+\hat{\rho}_2}{1-\hat{\rho}_2})$, where $\hat{\rho}_1$ and $\hat{\rho}_2$ are the estimators of the correlation coefficients.

  - **Conditions for validity:** In both populations, the pair $(X, Y)$ must follow a joint normal distribution.

  - **R instruction:** You can use the function `cor.test.2.sample()` available in the package associated with this book.

  - **Example of use:** In the data set BMI-child, we wish to compare the intensity of the relation height-weight between the group of girls and the group of boys.

    ```r
    > indg <- which(GENDER=="F")  # To get the indices of girls.
    > indb <- which(GENDER=="M")  # To get the indices of boys.
    > cor.test.2.sample(height[indg], weight[indg],
    + height[indb], weight[indb])
    $statistic
    [1] -1.67379
    $p.value
    [1] 0.09417185
    
    At the 5% risk level, we cannot show a significant difference between the two coefficients of linear correlation.
11.3.2 Independence tests

11.3.2.1 $\chi^2$ test for independence

- **Description of the test:** Let $X_1$ and $X_2$ be two qualitative variables (or variables made qualitative by grouping): $X_1$ has $l$ modalities and $X_2$ has $c$ modalities. We wish to know whether these two variables are dependent, *i.e.* whether the modalities of variable $X_2$ are not distributed in the same way in each of the $l$ sub-populations made of individuals taking each of the $l$ modalities of variable $X_1$. We know the value of these modalities for $n$ individuals; these data are usually given in a contingency table (or table of observed frequencies) and we compare this table to the theoretical contingency table for $n$ individuals calculated under the assumption of independence of the two variables. The hypotheses are $H_0$: variables $X_1$ and $X_2$ are independent and $H_1$: the variables are not independent. Under $H_0$, the test statistic is

$$X^2 = \sum_{i=1}^c \sum_{j=1}^l \frac{(N_{ij} - t_{ij})^2}{t_{ij}} \sim \chi^2((c - 1)(l - 1))$$

where $N_{ij}$ is the observed value and $t_{ij}$ is the theoretical value calculated under $H_0$.

- **Conditions for validity:** The theoretical values $t_{ij}$ must be greater than 5; otherwise, you can use Yates’ $\chi^2$ (if the values are greater than 2.5 and only for $2 \times 2$ tables), or Fisher’s exact test.

- **R instruction:** Use the function `chisq.test()` with the argument `correct=FALSE`.

- **Example of use:** We return to the example of the “Ditrame” study, where the underlying question is to know whether treatment has an effect on the HIV status of the child.

```R
> mytable
HIVSTATUS
TTTGRP 1 0
0 59 139
1 41 152
> chisq.test(mytable,correct=FALSE)
Pearson's Chi-squared test

data: mytable
X-squared = 3.7574, df = 1, p-value = 0.05257
```

At the 5% risk level, we cannot show that treatment has an effect on the HIV status of the child.
11.3 Standard hypothesis testing

Tip
You can also use the command summary(table(HIVSTATUTS,TTTGRP))
to get the result of the $\chi^2$ independence test.

Note
You can perform a $\chi^2$ test of mutual independence for $d \geq 2$ qualitative variables (see [5]). The $\chi^2$ statistic is then

$$X^2 = \sum_{A \in \mathcal{I}_d} T_A$$

with

$$T_A = \begin{cases} X_A^2 & \text{if } |A| = 2; \\ X_A^2 - \sum_{B \subset A \mid |B| < 2} T_B & \text{if } |A| > 2. \end{cases}$$

In the last equation, $\mathcal{I}_d$ is the family of all subsets of $\{1, \ldots, d\}$ of size strictly greater than 1. Furthermore, if we are given the contingency array $\mathbb{M}$ of the $d$ quantitative variables, then $X_A^2 (|A| \geq 2)$ can be obtained with the instruction summary(margin.table($\mathbb{M},A$))$statistic where $A$ is the vector of indices of elements in $A$. Another advantage of this (orthogonal) decomposition of $X^2$, obtained by induction, is that each term $T_A$ describes the mutual dependence of variables indexed by the set $A$.

The R function which performs this operation is A.dep.tests(). It is included in the package IndependenceTests.

11.3.2.2 Yates’ $\chi^2$ test

Description of the test: The $\chi^2$ test with Yates’ correction (or Yates’ $\chi^2$) should be used when you wish to perform a $\chi^2$ independence test for a $2 \times 2$ table, but at least one of the theoretical counts is less than 5; the theoretical counts should not be too small ($> 2.5$). The general setting is the same as the $\chi^2$ independence test. Under $H_0$, the test statistic is

$$X^2 = \sum_{i=1}^{c} \sum_{j=1}^{l} \frac{(|N_{ij} - t_{ij}| - 0.5)^2}{t_{ij}^2} \sim \chi^2(1).$$

R instruction: You can use the function chisq.test().

Example of use: In the data set INTIMA-MEDIA, we select people aged 50 or more and we wish to test whether their smoking habits are linked to gender.

```r
table.cont <- as.matrix(table(GENDER[AGE>=50], + tobacco[AGE>=50]))
> chisq.test(table.cont)$expected  # Table of theoretical counts.
```
11.3.2.3 Fisher’s exact test

Description of the test: Fisher’s exact test is used when the conditions for the $\chi^2$ independence test and Yates’ $\chi^2$ test are not verified, i.e. for small theoretical counts. Fisher’s test can be used for tables with more than two rows or columns.

R instruction: Use the function `fisher.test()`.

Example of use: The definition of obesity is that an individual with BMI greater than 30 kg/m$^2$ is obese. We make the hypothesis that obesity is more common in people less than 50 years old. This means that the BMI variable is linked to age. We wish to answer this question using the “Intima-media” study. To this end, we study the joint distribution of the following variables: under 50 / over 50 and BMI<30 / BMI>30. We get the following distribution:

```r
> bmi <- weight/(height/100)^2
> obesity <- factor(bmi<30)
> levels(obesity) <- c("BMI>30","BMI<30")
> age50 <- factor(AGE>=50)
> levels(age50) <- c("under 50","over 50")
> table(age50,obesity)

    obesity
age50      BMI>30 BMI<30
under 50   8     77
over 50    1     24
```

```r
> bmi.table <- as.matrix(table(obesity,age50))
> fisher.test(bmi.table,alternative="greater")
Fisher’s Exact Test for Count Data

data:  bmi.table
p-value = 0.3478
alternative hypothesis: true odds ratio is greater than 1
95 percent confidence interval:
0.3830018  Inf
```
We cannot show that obesity is significantly more frequent amongst people under the age of 50.

**Note**

Fisher’s exact test makes it possible to have a unilateral alternative hypothesis.

**Tip**

The function `CrossTable()` from the package `gmodels` calculates independence tests (chi-square, Fisher exact and McNemar). It also produces outputs similar to those provided by SAS or SPSS.

### 11.3.3 Non-parametric tests

#### 11.3.3.1 Goodness-of-fit tests

- **Shapiro-Wilk test**

  - **Description of the test:** The Shapiro-Wilk test is built specifically to test whether a continuous variable $X$ is normally distributed. It is the most powerful test of normality. The hypotheses are: $\mathcal{H}_0 : X$ follows a normal distribution and $\mathcal{H}_1 : X$ does not follow a normal distribution. The test statistic is

    $$ W = \frac{T^2}{\hat{\sigma}^2} $$

    where $\hat{\sigma}^2 = \frac{1}{n-1} \sum_{i=1}^{n} (X_i - \bar{X})^2$ and $T^2 = \frac{1}{n-1} \left( \sum_{i=1}^{\lfloor n/2 \rfloor} a_i (X_{(n-i+1)} - X_{(i)}) \right)^2$.

    The $a_i$ are the coefficients of the Shapiro-Wilk table available in most books of statistical tables.

  - **R instruction:** You can use the function `shapiro.test()`.

  - **Example of use:** We return to the `INTIMA-MEDIA` data set used in the case "mean comparison with one sample". We wish to invalidate the assumption of normality of intima-media thickness for people with BMI above 30.
Confidence intervals and hypothesis testing

> measure1
[1] 0.62 0.52 0.55 0.59 0.59 0.65 0.63 0.79 0.63
> shapiro.test(measure1)

Shapiro-Wilk normality test
data: measure1
W = 0.8835, p-value = 0.1708
We cannot show that the data are not normal, at the 5 % risk level.

• $\chi^2$ test for fit to a distribution

The $\chi^2$ test for fit to a distribution is used to check whether a qualitative variable follows a given theoretical distribution. It can be used to check whether a quantitative variable follows a given theoretical distribution, but in that case, it must first be grouped into classes to make it qualitative.

▶ Description of the test: Let $X$ be a qualitative random variable with $k$ modalities. We assume that $X$ follows the distribution where modality $i$ has probability $p_i$. Given a sample of size $n$, we test whether $X$ follows the distribution defined by the $p_i$. The hypotheses of the test are $H_0: X$ follows the distribution defined by the $p_i$ and $H_1: X$ does not follow this distribution. The test statistic is:

$$\sum_{i=1}^{k} \frac{(N_i - np_i)^2}{np_i} \sim \chi^2(k - 1)$$

where $N_i$ is the observed count for modality $i$.

▶ Conditions for validity: All theoretical counts $np_i$ are greater than or equal to 5.

▶ R instruction: You can use the function `chisq.test()`.

▶ Example of use: A study on hypertension was performed, and we wish to check whether the sample of patients is representative of the general population from an ethnic point of view. We know that in the general population of Mauritius, the ethnic distribution is: Hindu 51 %, Muslim 17 %, Creole 27 %, Chinese 3 % and Other 2 %. The data are available in the file `http://www.biostatisticien.eu/springerR/HTAen.xls`.

> table(ETHNIC)

<table>
<thead>
<tr>
<th>ETHNIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>225</td>
</tr>
<tr>
<td>77</td>
</tr>
<tr>
<td>99</td>
</tr>
<tr>
<td>1</td>
</tr>
</tbody>
</table>

> ni <- cbind(t(as.vector(table(ETHNIC))),0)
> chisq.test(ni,p=c(0.51,0.17,0.27,0.03,0.02))

Chi-squared test for given probabilities
data: ni
X-squared = 22.0659, df = 4, p-value = 0.0001945
At the 5% risk level, we can conclude that the sample of patients is significantly not representative of the general population from an ethnic point of view.

- **Kolmogorov-Smirnov test for one sample**

  *Description of the test:* The aim of this test is the same as the \( \chi^2 \) test for fit to a distribution. We wish to compare an empirical distribution to a completely specified theoretical distribution. Let \( F_0 \) be the specified cumulative distribution function and \( F \) the cumulative distribution function of \( X \). We are interested in the point at which the difference between the two cumulative distribution functions is greatest in absolute value, and we compare this value to the critical value given by the Kolmogorov-Smirnov table for one sample. The hypotheses of the test are: \( H_0 : F = F_0 \) and \( H_1 : F > F_0 \). The test statistic is

\[
D = \sup_x|\hat{F}_{X_n}(x) - F_0(x)|
\]

where \( \hat{F}_{X_n}(\cdot) \) is the empirical c.d.f. of the sample \( X_n \).

*R instruction:* Use the function `ks.test()`.

*Example of use:* We return to the can factory example and try to invalidate the assumption of normality, which is necessary for the variance test. The cans are made with average weight \( \mu = 170 \text{g} \) and precision \( \sigma^2 = 10 \). We test the normality of the series of twenty cans made by the factory.

```r
> weights <- c(165.1, 171.5, 168.1, 165.6, 166.8, 170.0, 168.8,
+ 171.1, 168.8, 173.6, 163.5, 169.9, 165.4, 174.4,
+ 171.8, 166.0, 174.6, 174.5, 166.4, 173.8)
> ks.test(weights, "pnorm", 170, sqrt(10))
```

One-sample Kolmogorov-Smirnov test

data: weights

\( D = 0.1942 \), \( p-value = 0.4376 \)

alternative hypothesis: two-sided

At the 5% risk level, we cannot show that the data are not normally distributed.

- **Kolmogorov-Smirnov test for two samples**

  *Description of the test:* The aim of this test is to compare two distributions \( F_1 \) and \( F_2 \). We are interested in the point at which the difference between the two empirical cumulative distribution functions (\( \hat{F}_{X_1} \) and \( \hat{F}_{X_2} \)) is greatest and we compare this value to the critical value given by the Kolmogorov-Smirnov table for two samples. The hypotheses of the
test are: $\mathcal{H}_0 : F_1 = F_2$ and $\mathcal{H}_1 : F_1 \gtrless F_2$. The test statistic is
\[
D = \sup_x |\hat{F}_{X_1}(x) - \hat{F}_{X_2}(x)|. 
\]

► **R instruction:** You can use the function `ks.test()`.

► **Example of use:** Using the data set `INTIMA`-`MEDIA`, we wish to see whether men who have quit smoking are younger than men who smoke. In the sample, there are twelve smokers and nine former smokers. The sample size is small; we do not know the distribution of the age variable in this population and therefore cannot use a Student test to compare the means. The test is unilateral, since the hypothesis is that smokers are younger than former smokers.

```r
> table(tobacco,GENDER)
GENDER     tobacco
           0  32 40
     1  9  9
     2 12  8
> ks.test(AGE[GENDER==1&tobacco==1],AGE[GENDER==1&tobacco==2],
          alternative="greater")
Two-sample Kolmogorov-Smirnov test
data: AGE[GENDER == 1 & tobacco == 1] and AGE[GENDER == 1 & tobacco == 2]
D^+ = 0.6389, p-value = 0.01502
alternative hypothesis: the CDF of x lies above that of y
```

In the population under study, we have shown at the 5% risk level that men who have quit smoking are younger than men who smoke.

### 11.3.3.2 Tests of position

- **Sign test or test of the median for one sample**

  ► **Description of the test:** We wish to compare the theoretical median of a quantitative variable $X$ (denoted by $m_e$) to a reference value $m_0$, with no assumption about the data. The hypotheses of the test are $\mathcal{H}_0 : m_e = m_0$ or equivalently $P(X - m_0 > 0) = 0.5$ and $\mathcal{H}_1 : m_e \gtrless m_0$ or equivalently $P(X - m_0 > 0 \gtrless 0.5$. Under $\mathcal{H}_0$, the test statistic is:

  $$K \sim Bin(n, 0.5)$$
where $K$ is the number of values strictly greater than $m_0$. This test is therefore equivalent to a test of proportion.

**R instruction:** You can use the functions `prop.test()` or `binom.test()`.

**Example of use:** The median price of one bedroom flats in the Grenoble region in 2008 was 130. We are given a sample of size $n = 32$ of prices of one bedroom flats (in thousands of euros), from the free monthly magazine *L’Offre Immobilière*, issue number 91 (January 2009). We wish to know whether prices are increasing.

```r
> m0 <- 130
> prices <- c(230.00, 148.00, 126.00, 134.62, 155.00, 157.70, + 160.00, 225.00, 125.00, 109.00, 157.00, 115.00, + 125.00, 225.00, 118.00, 179.00, 176.00, 125.00, + 123.00, 180.00, 151.00, 120.00, 143.00, 170.00, + 190.00, 233.00, 148.72, 189.00, 121.00, 149.00, + 225.00, 240.00)
> sum(prices-m0>0)
[1] 22
> median(prices)
[1] 153
> prop.test(22, 32, 0.5, "greater")
1-sample proportions test with continuity correction
data: 22 out of 32, null probability 0.5
X-squared = 3.7812, df = 1, p-value = 0.02591
alternative hypothesis: true p is greater than 0.5
95 percent confidence interval:
 0.5266965 1.0000000
sample estimates:
p
0.6875
```
We can conclude, at the 5% risk level, that prices are increasing.

- **Sign test or median test for two independent samples**

**Description of the test:** The median test is a test which compares the medians $m_{e_1}$ and $m_{e_2}$ of two quantitative variables $X_1$ and $X_2$ using data from two independent samples of these variables. The hypotheses of the test are $H_0 : m_{e_1} = m_{e_2}$ and $H_1 : m_{e_1} \neq m_{e_2}$. Under $H_0$, we compute the common median $\hat{m}_e$ for the two samples joined together. We then build a $2 \times 2$ table of counts of values which are smaller or greater than the median in the samples. This table is used as a $\chi^2$ contingency table. We can then perform a $\chi^2$ test, or (depending on the sample size), a $\chi^2$ test with Yates’ correction or an exact Fisher test.
**Example of use:** We return to the data set INTIMA-MEDIA and wish to test whether women who have quit smoking are younger than women who smoke. In this example, there are nine smokers and eight former smokers. The sample size is small and we cannot assume that the age variable is normally distributed in this population. We therefore cannot compare the means; it becomes interesting to perform a median test.

```r
> Me <- median(AGE[GENDER==2 & tobacco>0])
> tab.obs <- table(tobacco[tobacco>0 & GENDER==2 & AGE!=Me],
+ AGE[GENDER==2 & tobacco>0 & AGE!=Me]>Me)
> rownames(tab.obs) <- c("Former smoker","Smoker")
> colnames(tab.obs) <- c("AGE<ME","AGE>ME")
> tab.obs

<table>
<thead>
<tr>
<th>AGE&lt;ME</th>
<th>AGE&gt;ME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Former smoker</td>
<td>6</td>
</tr>
<tr>
<td>Smoker</td>
<td>2</td>
</tr>
</tbody>
</table>

> fisher.test(tab.obs,alt="greater")
Fisher's Exact Test for Count Data
data: tab.obs
p-value = 0.06597
alternative hypothesis: true odds ratio is greater than 1
95 percent confidence interval:
0.878644   Inf
sample estimates:
odds ratio
7.613556
```

At the 5 % risk level, we cannot assert that women who have quit smoking are younger than women who smoke.

- **Sign test for two paired samples**

  **Description of the test:** We wish to compare two paired quantitative series. We use the series of differences. We delete all concordant pairs (pairs for which the two values are equal) and keep only the discordant pairs (non-zero difference between the two values). The sign test only takes into account the sign of the difference of discordant pairs. Let \( N^+ \) be the number of positive pairs and \( N^- \) the number of negative pairs. The test statistic is:

  \[
  S = \min(N^+, N^-) \sim Bin(n, 0.5).
  \]

  **R instruction:** You can use the functions `prop.test()` or `binom.test()` after calculating the realization of \( S \). Note that when \( n \geq 20 \), the distribution of \( S \) can be approximated by \( N(\frac{n}{2}, \frac{n}{4}) \).
Example of use: We return to the example of results from two labs, which we previously analysed using a test of comparison of means under the assumption of normality. The sign test does not require any assumption.

```r
> dose.lab1 <- c(22, 18, 28, 26, 13, 8, 21, 26, 27, 29, 25, 24, 22, 28, 15)
> dose.lab2 <- c(25, 21, 31, 27, 11, 10, 25, 26, 29, 28, 26, 23, 22, 25, 17)
> dif <- (dose.lab1-dose.lab2)
> nminus <- sum(dif<0)
> nplus <- sum(dif>0)
> binom.test(min(nplus,nminus),nplus+nminus)
```

```
Exact binomial test

data: min(nplus, nminus) and nplus + nminus
number of successes = 4, number of trials = 13, p-value = 0.2668
alternative hypothesis: true probability of success is not equal to 0.5
95 percent confidence interval:
0.0909204 0.6142617
sample estimates:
probability of success
0.3076923
```

At the 5% risk level, we cannot conclude that the two labs give different results.

Wilcoxon or Mann-Whitney test for two independent samples

Description of the test: The Wilcoxon rank test is a non-parametric test which tests whether two distributions $F_1$ and $F_2$ are equal. The hypotheses of the test are: $H_0: F_1 = F_2$ and $H_1: F_1 \neq F_2$. The idea of the test is as follows: we merge the two series and sort the values from smallest to largest; we assign rank 1 to the smallest value, rank 2 to the next value, and so on. We then calculate the score of each series by summing the ranks of the values from that series. Using the appropriate table, we then decide whether the scores are compatible with the hypothesis $H_0$ of equal distributions. By convention, the test statistic $S$ is the score of the sample with the smallest size. The statistic $W = S - \frac{n_0(n_0+1)}{2}$ is also used sometimes.

Conditions for validity: If $n_0 = \min(n_1, n_2) \leq 10$, then the statistic $W$ does not follow a standard distribution, but the corresponding probabilities are given in the Mann-Whitney/Wilcoxon table (function `pwilcox()`).

If $\min(n_1, n_2) > 10$, we can consider that $W \sim N\left(\mu_W = \frac{n_1 n_2}{2}, \sigma^2_W = n_1 n_2 \left(\frac{n_1 + n_2 + 1}{12}\right)\right)$. If there are ties in the ranks, we also use a normal approximation, but with

$$\sigma^2_W = \frac{n_1 n_2}{12} \times \left((n_1 + n_2 + 1) - \sum_{j=1}^{g} \frac{g_j^3 - g_j}{3(n_1 + n_2)}\right)$$

where $g$ is the number
of groups of tied values and \( t_j \) the number of tied values in group \( j \).

- **R instruction:** You can use the function `wilcox.test()` with the argument `exact=FALSE` for an approximate calculation using the normal approximation.

- **Example of use:** Using the dataset `INTIMA-MEDIA`, we would like to know whether men who smoke are older than men who have quit smoking. In this sample, there are nine smokers and twelve former smokers.

```R
> wilcox.test(AGE[SEX==1&tobacco==2],AGE[SEX==1&tobacco==1],exact=FALSE,alternative="greater")
```

```
Wilcoxon rank sum test with continuity correction
data:  AGE[SEX == 1 & tobacco == 2] and AGE[SEX == 1 & tobacco == 1]
W = 88.5, p-value = 0.007756
alternative hypothesis: true location shift is greater than 0
```

At the 5% risk level, we can conclude that men who smoke are older than men who have quit smoking.

### Warning

To get the statistic \( W \), you need to put the smallest sample first in the function `wilcox.test()`.

- **Wilcoxon test for two paired samples**

  - **Description of the test:** We wish to compare two paired quantitative series. We use the series of paired differences. We discard all concordant pairs (pairs for which the two values are equal) and keep only the discordant pairs (non-zero difference). Let \( n \) be the number of discordant pairs. We sort the values according to their absolute value and rank them. In case of a tie, we use the mean of the corresponding ranks. Let \( S^+ \) be the score of the series of positive differences and \( S^- \) the score of the series of negative differences. The scores are calculated in the same way as for the Wilcoxon test. The hypotheses of the test are: \( H_0 : F_1 = F_2 \) and \( H_1 : F_1 \neq F_2 \). We can use either \( S^+ \) or \( S^- \) as the test statistic.

  - **Conditions for validity:** If \( n \leq 30 \), then the test statistic does not follow a standard distribution, but the corresponding probabilities can be found in the Wilcoxon table for paired series. If \( n \geq 30 \), then \( S^+ \) and \( S^- \) follow a \( N\left(\frac{n(n+1)}{4}, \frac{n(n+1)(2n+1)}{24}\right) \) distribution.

  - **R instruction:** By default, R uses the statistic \( V = S^+ \) in the function `wilcox.test()` with argument `paired=TRUE`. Use the argument `exact=FALSE`
to use the normal approximation.

▶ **Example of use:** We return to the example of the results from two labs, which we analysed with the sign test. This test is more powerful than the sign test, since it also takes into account the absolute value of the differences.

```r
> dose.lab1 <- c(22, 18, 28, 26, 13, 8, 21, 26, 27, 29, 25, 24, 22, 28, 15)
> dose.lab2 <- c(25, 21, 31, 27, 11, 10, 25, 26, 29, 28, 26, 23, 22, 25, 17)
> wilcox.test(dose.lab1,dose.lab2,paired=T, exact=FALSE)

Wilcoxon signed rank test with continuity correction

data:  dose.lab1 and dose.lab2
V = 22, p-value = 0.1047
alternative hypothesis: true location shift is not equal to 0
```

At the 5% risk level, we cannot conclude that the two labs give different results.

**11.3.4 Memorandum of standard tests**

This table lists all the tests we have introduced.
### Table 11.4: Standard tests.

### SECTION 11.4

#### Other tests

Many other tests are available in R. For example, you can get a first list of tests with the following instruction:

```r
> apropos(".test")
```

```
1 "runRUnitTestsGdata" "valueClassTest"
[3] "ansari.test" "as.krandtest"
[5] "as.randtest" "as.rtest"
[7] "asympt.test" "bartlett.test"
[9] "binom.test" "Box.test"
[11] "chisq.test" "cor.test"
[13] "cor.test.2.sample" "cor0.test"
[15] "file.test" "fisher.test"
[17] "fligner.test" "friedman.test"
[19] "gpuTtest" "kruskal.test"
[21] "ks.test" "mantel.randtest"
[23] "mantel.rtest" "mantelhaen.test"
[25] "mauchley.test" "mauchly.test"
[27] "mcnemar.test" "mood.test"
[29] "multispati.randtest" "multispati.rtest"
[31] "oneway.test" "ormidp.test"
```
Other tests are available in packages. For example, package nortest includes various tests of fit to normality. The functions associated with these tests are:

```r
> require(nortest)
> ls("package:nortest")
```

Note
Memorandum

t.test(): test and confidence interval for the mean
var.test(): test for equality of variances
prop.test(): approximate confidence interval for a proportion
binom.test(): exact confidence interval for a proportion
cor.test(): test and confidence interval for correlation
chisq.test(): χ² test
fisher.test(): Fisher’s test of independence
ks.test(): Kolmogorov-Smirnov test of fit to a distribution
shapiro.test(): Shapiro-Wilk test of normality
med.test(): median test
wilcox.test(): Wilcoxon test of position
boot: package for bootstrap

Exercises

11.1- Which function would you use to get the quantiles of a binomial distribution?
11.2- What is the use of the function pnorm()?
11.3- Give the R instruction to get a confidence interval for the mean using a sample of size 50.
11.4- Explain the difference between the functions prop.test() and binom.test().
11.5- Name two functions which compare two cumulative distribution functions using two samples.
11.6- Which function is used to test whether a sample follows a normal distribution?
11.7- Which functions are used to test the dependence of qualitative variables?
11.8- Which package includes functions to compute confidence intervals using bootstrap?
11.9- Which formal argument of the function t.test() is used for a paired test?
11.10- What is the difference between a χ² for independence and a χ² for fit to a distribution? How would you perform these two tests in R?
A- Study of confidence intervals

The aim of this practical is to understand how to interpret a confidence interval. Indeed, for a confidence interval at level $1 - \alpha$ of an unknown parameter, it is incorrect to say that there is a $100 \times (1 - \alpha)\%$ chance that the parameter lies in the realized interval. The unknown parameter has a unique value which does not change: the probability that it lies in the realized interval is either 0 or 1. However, it is correct to say that there is a $5\%$ risk of being wrong by stating that the parameter lies in the realized confidence interval.

- Study of the confidence interval for the mean

11.1- Simulate $M = 50,000$ samples of size $n = 20$ from a normal distribution with mean $\mu = -1.2$ and variance $\sigma^2 = 2$.
11.2- For each sample, compute a $90\%$ confidence interval of the mean $\mu$.
11.3- Calculate the proportion of intervals which contain the value $\mu = -1.2$. What do you observe?
11.4- Repeat this procedure for the value $\mu = 1$, with samples of size $n = 100$ from a $\chi^2(1)$ distribution.
11.5- Same question with $n = 10$ and a $\chi^2(1)$ distribution. What do you observe? How do you explain this?
11.6- Simulate a sample of size $n = 20$ from a normal distribution with mean $\mu = -1.2$ and variance $\sigma^2 = 2$. Calculate a $95\%$ confidence interval for $\mu$.
11.7- Repeat this operation for samples of increasing size: $n = 50; 100; 1,000; 10,000; 100,000$. What do you observe?
11.8- For each of the six samples above, calculate the observed value of the statistic for a Student test of hypothesis $H_1: \mu \neq 0$, as well as the $p$-value of the test (at significance level $5\%$). What do you observe? How do you explain this?
11.9- For a sample of size $n = 100,000$, calculate a $95\%$ confidence interval and compute the $p$-value of the test of hypothesis $H_1: \mu \neq -1.1$. Compare this $p$-value to the one you found in the previous question with $n = 50$. What do you conclude?
• Study of confidence intervals from bootstrap

11.1- Simulate $M = 500$ samples of size $n = 20$ from an exponential distribution with expectation $1/\lambda = 10$.

11.2- For each sample, calculate a 90% confidence interval of the mean $1/\lambda$ using the bootstrap method.

11.3- Using the method described above, check the level of the confidence interval.

11.4- Compare this level to the one you get with a standard confidence interval for the mean (procedure `t.test()`).

B- Study of risks in hypothesis testing

The aim of this practical is to explore the risks associated with hypothesis testing:

• $P[\text{accept } H_1 | H_0 \text{ is true}] = \alpha$, the risk of deciding $H_1$ when in reality $H_0$ is true;

• $P[\text{reject } H_1 | H_1 \text{ is true}] = \beta$, the risk of not deciding $H_1$ when in reality $H_1$ is true.

• Study of risk of the first kind

11.1- Simulate $M = 500$ samples of size $n = 20$ following a normal distribution with mean $\mu = 4$ and variance $\sigma^2 = 1.2$.

11.2- For each sample, perform a Student test for hypotheses $H_0 : \mu = 4$ and $H_1 : \mu \neq 4$ at level $\alpha = 5\%$.

11.3- Count how many times you decide $H_1$. What result did you expect?

11.4- Increase the number $M$ of simulations.

11.5- Repeat this procedure for the value $\mu = 1$, with samples of size $n = 100$ from a $\chi^2(1)$ distribution.

11.6- Same question with $n = 10$. What do you observe? How do you explain this?

11.7- In fact, for each of the $M = 500$ samples, we make the decision either to accept $H_1$, or to reject it. Let $d_j (1 \leq j \leq M)$ be the random variable which takes the value 1 if we decide to accept $H_1$ and 0 otherwise (based on the $j$th sample). The variable $d_j$ follows a Bernoulli distribution with parameter $p = P[d_j = 1] = P[\text{accept } H_1]$. The variables $d_j$ are independent, hence the variable $d = \sum_{j=1}^{M} d_j$ follows a binomial distribution $\text{Bin}(M, p)$. It counts how many times we accept $H_1$. If $H_0$ is true, and the test is well constructed (well chosen critical value), then we should have $p = P[\text{accept } H_1 | H_0 \text{ is true}] = \alpha$. Calculate a 95% confidence interval for parameter $p$ and conclude.

• Study of power

11.1- Simulate $M = 500$ samples of size $n = 20$ from a normal distribution with mean $\mu = 5$ and variance $\sigma^2 = 1.2$.

11.2- On each sample, perform a Student test between $H_0 : \mu = 4$ and $H_1 : \mu \neq 4$ at level $\alpha = 5\%$. 
11.3- Count the number of times you accept $H_1$. Estimate the power of the test for the situation in $H_1$ where $\mu = 5$.

11.4- Increase the size of the sample to $n = 100$ and estimate the power of the test. What do you observe?

11.5- Repeat the procedure for the test $H_0 : \mu = 1$ and $H_1 : \mu \neq 1$, with samples of size $n = 100$ from a $\chi^2(2)$ distribution.

11.6- Same question with $n = 10$. What do you observe? How do you explain this?

C- A few practical examples

• Cow study
The quantity of bacteria per cm$^3$ of milk from eight different cows is estimated after milking and 24 hours later. We wish to test whether the quantity of bacteria significantly increases with time.

<table>
<thead>
<tr>
<th>Cow</th>
<th>Just after milking</th>
<th>24 h after milking</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>12,000</td>
<td>11,000</td>
</tr>
<tr>
<td>2</td>
<td>13,000</td>
<td>20,000</td>
</tr>
<tr>
<td>3</td>
<td>21,500</td>
<td>31,000</td>
</tr>
<tr>
<td>4</td>
<td>17,000</td>
<td>28,000</td>
</tr>
<tr>
<td>5</td>
<td>15,000</td>
<td>26,000</td>
</tr>
<tr>
<td>6</td>
<td>22,000</td>
<td>30,000</td>
</tr>
<tr>
<td>7</td>
<td>11,000</td>
<td>16,000</td>
</tr>
<tr>
<td>8</td>
<td>21,000</td>
<td>29,000</td>
</tr>
</tbody>
</table>

11.1- Answer the question under the assumption of normality of the data.

11.2- Answer the question using a sign test.

11.3- Answer the question using a Mann-Whitney test.

• East German athletes
In the 1970s, female athletes from East Germany were well known for their corpulence. The Olympic ethics committee of the time, intrigued by this “masculinity”, required the services of Dr Volker Fischbach. He selected nine female athletes with identical morphological characteristics, then measured the quantity of androgens (hormones which stimulate male characteristics) per litre of blood. The results are: 3.22 3.07 3.17 2.91 3.40 3.58 3.23 3.11 3.62.

11.1- Given that for women who do not use performance-enhancing drugs, the mean quantity of androgens is 3.1, propose a way to test whether East German athletes used such drugs (assume normality of data).

11.2- What was Dr Fischbach conclusion?

• Drinking and driving
To study the effect of alcohol on reflexes, fourteen subjects went through a test of dexterity before and after drinking 100 ml of wine. The before and after scores are given in the following table (these are reaction times: a higher score means slower reflexes).
Propose a way to test whether alcohol has an effect on reflexes (assume normality of the data).

- **Speed of light**

In 1879, American physicist Michelson performed several experiments to check the speed of light \( c \) proposed by French physicist Cornu in 1876. Cornu proposed a value of 299,990 km/s. Michelson got the 20 following measures (we subtracted 299,990 from Michelson’s values, to avoid having to handle large numbers): 850 740 900 1,070 930 850 950 980 980 880 1,000 980 930 1,050 960 810 1,000 1,000 960.

These twenty observations can be considered as the observed values of twenty random variables with identical but unknown mean \( \mu \). If the conditions to measure the speed of light are satisfactory, then it is reasonable to assume that \( \mu \) is the true speed of light.

11.1- Plot the data. Comment.  
11.2- Test the normality of the data.  
11.3- Perform a Student test to check whether Michelson’s measures invalidate the value of \( c \) proposed by Cornu.  
11.4- What value for the speed of light could Michelson propose after these twenty experiments?

- **Cholesterol levels**

Seventeen people with the same illness I are randomly assigned to two groups. The first group receives a placebo A and the second group receives a treatment B containing a vitamin. The relevant measure is capillary resistance. We get the following measurements:

<table>
<thead>
<tr>
<th>Group A</th>
<th>Group B</th>
</tr>
</thead>
<tbody>
<tr>
<td>46.3 ; 42.5 ; 43.0 ; 43.9 ; 42.0 ; 41.5 ; 41.6 ; 44.4 ; 40.7</td>
<td>47.1 ; 44.5 ; 45.8 ; 49.0 ; 44.6 ; 43.7 ; 44.5 ; 47.4</td>
</tr>
</tbody>
</table>

Assuming that the measure of capillary resistance is normally distributed, what can you conclude?

- **Treatment-death independence**

Two small groups of animals are infected by a virulent germ. The first group receives chemotherapy; the second group is not treated. We measure mortality after eight days in both groups.

<table>
<thead>
<tr>
<th></th>
<th>With treatment</th>
<th>Without treatment</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dead</td>
<td>0</td>
<td>9</td>
<td>9</td>
</tr>
<tr>
<td>Survived</td>
<td>8</td>
<td>3</td>
<td>11</td>
</tr>
<tr>
<td>Total</td>
<td>8</td>
<td>12</td>
<td>20</td>
</tr>
</tbody>
</table>
Is mortality independent of treatment?

- Number of patients in the emergency ward

To study the variation of the number of emergency cases in a hospital, the number of patients was counted for the months of June, July and August. The results are:

<table>
<thead>
<tr>
<th></th>
<th>June</th>
<th>July</th>
<th>August</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of patients</td>
<td>1,500</td>
<td>1,600</td>
<td>1,450</td>
</tr>
<tr>
<td>Number of emergency patients</td>
<td>675</td>
<td>720</td>
<td>610</td>
</tr>
</tbody>
</table>

Can we conclude that the proportion of emergency cases is the same every month?
Chapter 12
Simple and multiple linear regression

Goals of this chapter
This chapter is a brief introduction to simple and multiple linear regression, and how to use this method in a real context (see [41] for a more complete presentation). We present the relevant R commands and use a real data set as a connecting thread as we present the key concepts for this method. We treat the case of qualitative explanatory variables, as well as interaction of explanatory variables. We discuss model validation with a study of residuals, and mention the issue of collinearity. We also present a few methods for variable selection.

SECTION 12.1
Introduction

In most situations, we study the relationship between a variable of interest \(Y\) (often quantitative) and one or several variable(s) \(X_1, X_2, \ldots, X_k\), with the aim of explaining the variations of the variable of interest. Variable \(Y\) is called the explained variable (or dependent variable, or response variable). Variables \(X_1, X_2, \ldots, X_k\) are called explanatory variables (or independent variables); in epidemiology, they represent risk or confounding factors. Thus, multivariate analysis models, and specifically linear regression models, allow us to:
• take into account simultaneously several factors which could explain the variation or the distribution of variable \( Y \);
• study the role of effect modification or confusion of one or several factor(s);
• predict the value or distribution of the explained variable knowing the value of the explanatory variables.

To introduce the key concepts of linear regression, we shall first introduce simple linear regression: we consider a quantitative explained variable \( Y \) and a single quantitative explanatory variable \( X \), though in principle, \( X \) could also be qualitative. In the second part, we shall introduce multiple linear regression, which is used to study the relation between a dependent quantitative variable \( Y \) and several (quantitative or qualitative) explanatory variables \( X_1, X_2, \ldots, X_k \).

**Connecting thread example: “weight at birth” study:**

We return to the dataset **Birth-weight** which we presented in Chapter B. We wish to explain the variability of child weight at birth as a function of characteristics of the mother, of family history and of behaviour during pregnancy. The explained variable is weight at birth (quantitative variable \( BWT \), expressed in grammes); the explanatory variables are described in Chapter B.

► **Loading the data**

```r
> fichier <- "http://www.biostatisticien.eu/springeR/Weight_birth.csv"
> mydata <- read.table(fichier,header=TRUE,sep="\t")
```

The weight of the mother is expressed in pounds. We first transform the data.frame to recode this variable in kilogrammes (1 pound = 0.453 592 37 kg).

```r
> mydata <- transform(mydata,LWT=LWT*0.4535923)
> attach(mydata)  # Access variable names.
```
12.2 Simple linear regression

12.2.1 Aim and model

▶ Aim

We wish to “explain” the variations of a quantitative variable $Y$ (for example child weight at birth, noted $BWT$) using an explanatory variable $X$, also quantitative (for example weight of the mother, noted $LWT$).

▶ Model

It is written

$$Y = \beta_0 + \beta_1 X + \epsilon$$

where $\epsilon$ represents the noise of the model, which is assumed to be normally distributed, with expectation zero and variance $\text{Var}(\epsilon|X) = \sigma^2$. The (unknown) parameters of the regression model are $\beta_0$, $\beta_1$ and $\sigma^2$.

Warning

The assumption of normality of the noise $\epsilon$ is necessary to get the distribution of the estimators, and thus perform hypothesis testing on the parameters of the model. However, this assumption is not very important, since it is not necessary when the data size is large.

12.2.2 Fitting data

▶ Graphical inspection

To study the relationship between child weight at birth and weight of the mother, we first draw the scatterplot of the points (child weight; mother weight) using the instruction `plot(BWT~LWT)`.

FILE: CHAP12.R
We observe a slight increase in child weight when mother weight increases, although this relationship is not very clear.

▶ Parameter estimation

We now study the following model:

\[ BWT_i = \beta_0 + \beta_1 LWT_i + \epsilon_i, \quad i = 1, \ldots, n \]

where the \( \epsilon_i \) are independent random variables with expectation zero and constant variance \( \sigma^2 \), for all \( i \).

The estimates \( \hat{\beta}_0 \) of \( \beta_0 \) and \( \hat{\beta}_1 \) of \( \beta_1 \) are obtained by minimizing the least squares criterion:

\[ S(\alpha_0, \alpha_1) = \sum_{i=1}^{n} (bwt_i - \alpha_0 - \alpha_1 lwt_i)^2. \]
12.2 Simple linear regression

The relevant R function for this operation is `lm()` (abbreviation of `linear models`). The main parameter of this function is a formula, symbolized by a tilde `~`, used to specify the relationship between BWT and LWT.

```r
> modell <- lm(BWT ~ LWT, data=mydata)  # We get an object # of class "lm".
> modell
Call:
  lm(formula = BWT ~ LWT, data = mydata)
Coefficients:
(Intercept)       LWT
     2369.672       9.765
```

The above R output gives the least squares estimates of $\beta_0$ and $\beta_1$. For the above example, we get $\hat{\beta}_0 = 2369.672$ and $\hat{\beta}_1 = 9.765$.

We can now draw the regression line on the scatter plot, using the function `abline()`:

```r
> plot(BWT~LWT, xlab="Mother weight", ylab="Child weight")
> abline(modell, col="blue")
```

![Least squares regression line on the scatter plot of child weight (in grammes) against mother weight (in kilogrammes).](image)

**Fig. 12.2**: Least squares regression line on the scatter plot of child weight (in grammes) against mother weight (in kilogrammes).

▶ Tests on parameters
Note that the function \texttt{lm()} performs a complete analysis of the linear model and that you can get a summary of the calculations related to the data set with the function \texttt{summary()}.

```r
> res <- summary(model1) # Results.
> res
Call:
\texttt{lm(formula = BWT \sim LWT, data = mydata)}
Residuals:
  Min 1Q Median 3Q     Max
-2192.184 -503.627  -3.910 508.250  2075.529
Coefficients:
         Estimate Std. Error t value Pr(>|t|)
(Intercept)   2369.672  228.431 10.374 <2e-16 ***
LWT            9.765    3.777  2.586  0.0105 *
---
Signif. codes:  0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
Residual standard error: 718.2 on 187 degrees of freedom
Multiple R-squared: 0.03452,  Adjusted R-squared: 0.02935
F-statistic: 6.686 on 1 and 187 DF,  p-value: 0.01048
```

Here is a description of the information in this output.

- **Call:** formula used in the model.
- **Residuals:** descriptive analysis of residuals $\hat{e}_i = \hat{y}_i - y_i$. Later in this chapter, we shall see that residuals are used to validate the assumptions of the regression model.
- **Coefficients:** this table has four columns:
  - Estimate gives the estimates of the parameters of the regression line;
  - Std. Error gives the estimate of the standard deviation of the estimators of the regression line;
  - t value gives the realization of Student’s test statistic associated with the hypotheses $H_0 : \beta_i = 0$ and $H_1 : \beta_i \neq 0$;
  - Pr(>|t|) gives the $p$-value of Student’s test.
- **Signif. codes:** codes for significance levels.
- **Residual standard error:** an estimate of the standard deviation of the noise $\sigma$, and the associated degree of freedom $n - 2$.
- **Multiple R-Squared:** coefficient of determination $r^2$ (percentage of variation explained by the regression).
- **Adjusted R-Squared:** adjusted $r^2$ (of limited interest for simple linear regression).
- **F-Statistic:** realization of Fisher’s test statistic associated with the hypotheses $H_0 : \beta_1 = 0$ and $H_1 : \beta_1 \neq 0$. The associated degrees of freedom (1 and $n - 2$) are given, as is the $p$-value.
Note that the values of all these fields can be extracted. For example, to get the four columns of the field `Coefficients`, use

```r
> res$coefficients
                       Estimate Std. Error    t value  Pr(>|t|)
(Intercept) 2369.672063 228.430647 10.373705 3.328580e-20
LWT          9.764856   3.776573  2.585639 1.048072e-02
```

The other suffixes are given by

```r
> names(res)
[1] "call"       "terms"      "residuals"
[4] "coefficients" "aliased"   "sigma"
[7] "df"         "r.squared" "adj.r.squared"
[10] "fstatistic" "cov.unscaled"
```

Also, note that the function `coefficients()` gives $\hat{\beta}_0$ and $\hat{\beta}_1$ directly from `model1`.

```r
> coefficients(model1)
(Intercept)     LWT
2369.672063 9.764856
```

### Analysis of variance table

In simple linear regression, Fisher’s test (the statistic of which is given in F-statistic) is equivalent to Student’s test for the regression slope. The relationship $F\text{-statistic} = t^2$ holds and the $p$-values of the tests are equal. Fisher’s test is often associated with an analysis of variance table, given by function `anova()`.

```r
> anova(model1)
Analysis of Variance Table
Response: BWT
          Df Sum Sq Mean Sq F value  Pr(>F)
LWT         1 3448881 3448881  6.6855 0.01048 *
Residuals 187 96468171  515873
---
Signif. codes:  0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
```

### Interpreting the results for the “Weight at birth” study

- The test associated with the intercept $\beta_0$ of the model is significant ($p$-value $< 0.05$), it is therefore advised to keep the intercept ($\hat{\beta}_0$) in the model. However, the intercept in this regression has no meaning. It might be better to use a regression on the variable mother weight, centred beforehand. In that case, $\hat{\beta}_0$ would represent the mean child weight for mothers who have weight equal to the mean weight of observed mothers.
The instruction to perform linear regression without an intercept is \( \text{lm}(y \sim x - 1) \) or equivalently \( \text{lm}(y \sim 0 + x) \).

- The linear relationship between BWT and LWT is proven by the result of Student’s test on coefficient \( \beta_1 \). The \( p \)-value < 0.05 indicates a significant linear relationship between child weight and mother weight.
- The percentage of variance explained by the regression \( (r^2) \) is 0.035. Only 3.5 % of the variability of child weight is explained by mother weight. We therefore need to add to the model other explanatory variables (multiple linear regression), to increase the model’s predictive power.
- The estimate of the slope indicates that the difference between the average weights of babies whose mothers have weights different by one kilogramme is 9.765 g.

To get an estimate by confidence interval of the regression coefficients, you can use the function `confint()`.

```r
> confint(model1)
2.5 % 97.5 %
(Intercept) 1919.039836 2820.30429
LWT 2.314692 17.21502
```

The 95 % confidence interval for \( \beta_1 \) is \( \text{ci}_{95 \%}(\beta_1) = [2.31, 17.22] \).

### 12.2.3 Confidence and prediction intervals for a new value

**Definition**

Consider a new observation \( x_0 \) of variable \( X \) for which we have not observed the corresponding value \( y_0 \) of the response variable \( Y \). This value \( y_0 \) is unknown, since it is not observed, and is a realization of the random variable \( Y_0 = \beta_0 + \beta_1 x_0 + \epsilon_0 \). The predictor of \( Y_0 \) for the new value \( x_0 \) is given by:

\[
\hat{Y}_0 = \hat{\beta}_0 + \hat{\beta}_1 x_0.
\]

We can also propose a prediction interval at level \( 1 - \alpha \) for \( Y_0 \), by finding two random bounds such that the random variable \( Y_0 \) falls in the interval with probability \( 1 - \alpha \).
\[ PI_{1-\alpha}(Y_0|x_0) = \left[ \hat{Y}_0^p \pm t^{(n-2)}_{1-\alpha/2} \hat{\sigma} \sqrt{1 + \frac{1}{n} + \frac{(x_0 - \overline{x})^2}{\sum_{i=1}^{n}(x_i - \overline{x})^2}} \right] \]

Note that the realization \( \hat{y}_0^p = \hat{\beta}_0 + \hat{\beta}_1 x_0 \) is called the prediction of the unobserved value \( y_0 = \beta_0 + \beta_1 x_0 + \epsilon_0 \).

Similarly, note that an estimator of the fixed and unknown value \( \mathbb{E}(Y_0|X = x_0) = \beta_0 + \beta_1 x_0 \) is given by:
\[ \hat{\mathbb{E}}(Y_0|X = x_0) := \hat{y}_0 = \hat{\beta}_0 + \hat{\beta}_1 x_0. \]

We can also give a confidence interval at level \( 1 - \alpha \) for \( \mathbb{E}(Y_0|X = x_0) \):
\[ IC_{1-\alpha}(\beta_0 + \beta_1 x_0) = \left[ \hat{y}_0 \pm t^{(n-2)}_{1-\alpha/2} \hat{\sigma} \sqrt{1 + \frac{1}{n} + \frac{(x_0 - \overline{x})^2}{\sum_{i=1}^{n}(x_i - \overline{x})^2}} \right]. \]

Warning
Note that \( \hat{y}_0^p = \hat{y}_0 \), but do not confuse the prediction interval for \( Y_0 \) and the confidence interval for the mean value \( \mathbb{E}(Y_0|X = x_0) = \beta_0 + \beta_1 x_0 \).

▶ R instruction

The function to define the prevision interval and confidence interval for a new value \( x_0 \) is `predict()`.

▶ Example with the study “Weight at birth”

We calculate the prediction of the weight of a baby whose mother weighs \( lwt = 56 \) kg.
\[
\text{> lwt0 <- 56}
\text{> predict(model1, data.frame(LWT=lwt0), interval="prediction")}
\]
\[
\begin{array}{ccc}
\text{fit} & \text{lwr} & \text{upr} \\
1 & 2916.504 & 1495.699 & 4337.309 \\
\end{array}
\]

For the confidence interval of the mean value of the weight of babies with a mother weighing 56 kg:
\[
\text{> predict(model1, data.frame(LWT=lwt0), interval="confidence")}
\]
\[
\begin{array}{ccc}
\text{fit} & \text{lwr} & \text{upr} \\
1 & 2916.504 & 2811.225 & 3021.783 \\
\end{array}
\]

We now represent the confidence interval and prediction interval for a series of new values of the mother’s weight:
> x <- seq(min(LWT), max(BWT), length=50)
> predint <- predict(model1, data.frame(LWT=x), interval="prediction")[, c("lwr","upr")]
> confint <- predict(model1, data.frame(LWT=x), interval="confidence")[, c("lwr","upr")]
> plot(BWT ~ LWT, xlab="Mother weight", ylab="Child weight")
> abline(model1)
> matlines(x, cbind(confint, predint), lty=c(2,2,3,3),
+ col=c("red","red","blue","blue"), lwd=c(2,2,1,1))
> legend("bottomright", lty=c(2,3), lwd=c(2,1),
+ c("confidence","prediction"), col=c("red","blue"))

![Visualization of confidence and prediction intervals.](image)

**12.2.4 Analysis of residuals**

▶ Checking model assumptions

Analysis of residuals consists in examining whether the underlying assumptions of the linear model are verified. Various plots of the residuals can be used to detect rather easily whether the assumptions on the errors $\epsilon_i$ are respected:
• Plotting the histogram of residuals to check for normality. The QQ-plot is another approach. You can also apply the Jarque-Bera test of normality on residuals (function `jarque.bera.test()` in package `tseries`).

• Plotting the residuals $\hat{e}_i$ as a function of the predicted values $\hat{y}_i$. When all the model assumptions are verified, residuals and predicted values are uncorrelated. This plot should have no particular structure. This plot also gives indications on the validity on the linearity assumption, and on the homogeneity of error variance. The plot of $\hat{e}_i$ against $\hat{y}_i$ should show a uniform spread of the residuals following a horizontal line on either side of the $x$ axis.

• For the assumption of independence of the $Y_i$: if the values $Y_i$ are measured on different, unrelated individuals, the assumption of independence is in principle verified. However, if the values of $Y_i$ represent measures of a quantity at different points in time (for example every month), the assumption of independence may not be verified. This assumption can be checked by examining the autocorrelation of the residuals, either graphically by plotting the residuals $\hat{e}_i$, or using statistical tests such as the Durbin-Watson test (function `dwtest()` in package `lmtest`).

▶ Example of analysis of residuals in study “Weight at birth”

We briefly present an analysis of residuals for the model under study, even though this is not very relevant given the low predictive power of the model ($r^2 = 3.5\%$).

We first examine the assumption of normality:
> par(mfrow=c(1,2))
> hist(residuals(model1), main="Histogram")
> qqnorm(resid(model1), datax=TRUE) # Caution: normalized quantiles on the y axis.

Fig. 12.4: Graphical inspection of normality of residuals.

> require(tseries)
> jarque.bera.test(residuals(model1)) # Jarque-Bera test of normality.

    Jarque Bera Test
 data:  residuals(model1)
 X-squared = 1.7877, df = 2, p-value = 0.4091

This test does not lead us to rejecting the assumption of normality of errors. The QQ-plot also suggests normal errors since the observed quantiles and theoretical quantiles (given by a normal distribution) form a straight line. We therefore accept the assumption of normality.

We now examine the plot of residuals as a function of predicted values. The next figure shows a scatter plot of residuals correctly spread, symmetrical about the x axis: the conditions of the model seem valid.
Some diagnostic plots can be obtained with the instructions:

```r
> plot(residuals(model1) ~ fitted(model1),
    + xlab="Predicted values", ylab="Residuals")
```

Fig. 12.5: Plot of residuals as a function of predicted values.

Note that the instruction `plot(model1)` can draw six plots; some of these are for detection of outliers. We shall return to this topic in the section on multiple linear regression.
12.2.5 Student tests for means and linear model

It is interesting to note that the one sample t-test, as well as the classical or paired two samples t-tests, are special cases of simple linear regression models.

- **One sample t-test.**
  
  Let $Y_1, \ldots, Y_n$ be i.i.d. $N(\mu, \sigma^2)$ random variables. We want to test
  
  $$H_0 : \mu = \mu_0 \text{ versus } H_1 : \mu \neq \mu_0,$$
  
  for some given reference value $\mu_0$. This can be performed by testing $\beta = 0$ in the model
  
  $$Y_i - \mu_0 = \beta + \epsilon_i$$
  
  where the $\epsilon_i$ are i.i.d. $N(0, \sigma^2)$, $1 \leq i \leq n$. Let us see this on an example.
  
  ```r
  > n <- 100
  > y <- rnorm(n, mean=0)
  > mu0 <- 0
  > t.test(y, mu=mu0)
  > summary(lm(y - mu0 ~ 1))
  > summary(lm(y ~ 1 + rep(mu0, n)))
  ```
  
  ```r
  [1] 0.08523596
  ```

- **Two samples t-test.**
  
  Let $X_{1(1)}, \ldots, X_{n_1(1)}$ be i.i.d. $N(\mu_1, \sigma^2)$ random variables, and $X_{1(2)}, \ldots, X_{n_2(2)}$ be i.i.d. $N(\mu_2, \sigma^2)$ random variables. The two samples are supposed to be independent. We want to test
  
  $$H_0 : \mu_1 = \mu_2 \text{ versus } H_1 : \mu_1 \neq \mu_2.$$
  
  This can be done by testing $\beta_1 = 0$ in the model
  
  $$Y_i = \mu_1 + \beta_1 A_i + \epsilon_i,$$
  
  where the $\epsilon_i$ are i.i.d. $N(0, \sigma^2)$ random variables, and where we define $A_i = \begin{cases} 
  0 & \text{if } 1 \leq i \leq n_1, \\
  1 & \text{if } n_1 + 1 \leq i \leq n_1 + n_2,
  \end{cases}$
  
  and $Y_i = \begin{cases} 
  X_{i(1)}^{(1)} & \text{if } 1 \leq i \leq n_1, \\
  X_{n_1 + i n_2}^{(2)} & \text{if } n_1 + 1 \leq i \leq n_1 + n_2.
  \end{cases}$
  
  Let us see this on an example.
  
  ```r
  > n1 <- 100 ; n2 <- 150
  > x1 <- rnorm(n1, mean=0) ; x2 <- rnorm(n2, mean=0.1)
  > y <- c(x1, x2) ; a <- c(rep(0, n1), rep(1, n2))
  > t.test(x1, x2, var.equal=TRUE)
  ```
  
  ```r
  [1] 0.3996454
  ```
12.2 Simple linear regression

\begin{verbatim}
> summary(lm(y ~ a))[[4]][2,4]
[1] 0.3996454

• Two samples paired t-test.
Let $X_1^{(1)}, \ldots, X_n^{(1)}$ be i.i.d. $\mathcal{N}(\mu_1, \sigma^2)$ random variables, and $X_1^{(2)}, \ldots, X_n^{(2)}$ be i.i.d. $\mathcal{N}(\mu_2, \sigma^2)$ random variables, measured on the same statistical units. We want to test

$$H_0 : \mu_1 = \mu_2 \text{ versus } H_1 : \mu_1 \neq \mu_2.$$ 

This can be done by testing $\beta = 0$ in the model

$$Y_i = \beta + \epsilon_i,$$

where the $\epsilon_i$ are i.i.d. $\mathcal{N}(0, \sigma^2)$ random variables, and where $Y_i = X_i^{(1)} - X_i^{(2)}$, $1 \leq i \leq n$. Let us see this on an example.

\begin{verbatim}
> n <- 100
> x1 <- rnorm(n,mean=0) ; x2 <- rnorm(n,mean=0.1)
> t.test(x1,x2,var.equal=TRUE,paired=TRUE)[[3]]
[1] 0.4541976
> summary(lm(x1-x2 ~ 1))[[4]][1,4]
[1] 0.4541976
\end{verbatim}

12.2.6 Summary

The table below presents the main functions to use for simple linear regression between the response variable $Y$ and the explanatory variable $X$.

12.3 Multiple linear regression

12.3.1 Aim and model

▶ Aim

We wish to study the variations of a quantitative variable $Y$ (the explained or response variable, assumed to be random) as a function of $p$ ($p > 1$) explanatory variables $X_1, X_2, \ldots, X_p$ (also called independent variables). The explanatory variables can be all quantitative, all qualitative (in which case we fall back on ANOVA, presented in Chapter 13), or a mixture of quantitative and qualitative variables. In this last case, the multiple linear regression model is also called ANCOVA.

▶ Model

The multiple linear regression model is written

$$Y = \beta_0 + \beta_1 X_1 + \ldots + \beta_p X_p + \epsilon$$

where $\epsilon$ is the random noise term of the model, often assumed to be normally distributed with expectation zero and variance $\sigma^2$, and independent of the $X_j$. The (unknown) parameters of the regression model are $\beta_0, \beta_1, \ldots, \beta_p$ and $\sigma^2$.

12.3.2 Fitting data

Consider a data set from the following model:

$$Y_i = \beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \ldots + \beta_p X_{ip} + \epsilon_i \quad i = 1, \ldots, n$$

where $X_{ij}$ is the $j$th explanatory variable for individual $i$ and the errors $\epsilon_i$ are independent random variables such that $\mathbb{E}(\epsilon_i) = 0$ and $\text{Var}(\epsilon_i|X) = \sigma^2$. The observed data from this model can be written in matrix form:

$$y = X\beta + \epsilon$$

with $y = \begin{pmatrix} y_1 \\ \vdots \\ y_n \end{pmatrix}$, $X = \begin{pmatrix} 1 & x_{11} & x_{12} & \cdots & x_{1p} \\ 1 & x_{21} & x_{22} & \cdots & x_{2p} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & x_{n1} & x_{n2} & \cdots & x_{np} \end{pmatrix}$, $\beta = \begin{pmatrix} \beta_0 \\ \vdots \\ \beta_p \end{pmatrix}$ and $\epsilon = \begin{pmatrix} \epsilon_1 \\ \vdots \\ \epsilon_n \end{pmatrix}$.

The regression parameters $\beta$ are estimated by minimizing the ordinary least squares:
12.3 Multiple linear regression

\[ S(\alpha) = \sum_{i=1}^{n} (y_i - \alpha_0 - \alpha_1 x_{i1} - \alpha_2 x_{i2} - \ldots - \alpha_p x_{ip})^2 = ||y - X\alpha||^2. \]

This gives the least squares estimator \( \hat{\beta} = (X^T X)^{-1} X^T y. \)

**Warning**

We assume that \( X : n \times (p + 1) \) is a full rank matrix (\( \text{rank}(X) = p + 1 < n \)). This implies that \( \text{rank}(X^T X) = p + 1 \) and thus that \( X^T X \) is invertible. This condition can be evaluated using \( R \) with the command \( \text{qr}(X) \$\text{rank} \). If this condition is not satisfied, it is possible to use other methods, not shown in this book, as ridge regression, lasso regression, regression on principal components or PLS regression.

▶ **Graphical inspection**

*Connecting thread example:* Regression of child weight at birth as a function of mother age, weight and smoking status during pregnancy.

In this study, we note \( X_1 \) the age of the mother (variable \( \text{AGE} \)), \( X_2 \) the weight of the mother (variable \( \text{LWT} \)), \( X_3 \) the smoking status of the mother (variable \( \text{SMOKE} \)), and \( Y \) the child weight at birth (response variable \( \text{BWT} \)); we can write the following regression equation:

\[ \mathbb{E}(\text{BWT}|\text{AGE}, \text{LWT}, \text{SMOKE}) = \beta_0 + \beta_1 \text{AGE} + \beta_2 \text{LWT} + \beta_3 \text{SMOKE}. \]

Before estimating the model, we present a scatter plot of all pairs of variables.

```r
> add.cor <- function(x,y) {
+  usr <- par("usr"); on.exit(par(usr))
+  par(usr = c(0, 1, 0, 1))
+  text(0.5,0.5,round(cor(x,y),2))
+ }
```
Call:
\texttt{lm(formula = BWT \sim AGE + LWT + as.factor(SMOKE))}

Coefficients:
\begin{verbatim}
(Intercept)      AGE     LWT as.factor(SMOKE)1
2362.720  7.093   8.860          -267.213
\end{verbatim}

Fig. 12.6: Scatter plot of all pairs of variables.

The purpose of this plot is twofold. It is used to visualize the relationship between the response variable and each of the explanatory variables, but also the correlation between explanatory variables. This second point is useful, amongst other things, because it helps notice collinearity issues (see the section on this topic, Section 12.3.7).

\section*{Parameter estimation}

As for simple linear regression, the model is estimated using function \texttt{lm()}:

\begin{verbatim}
> model2 <- lm(BWT \sim AGE+LWT+as.factor(SMOKE))
\end{verbatim}

Tests on parameters are performed by function \texttt{summary()}.

\begin{verbatim}
> summary(model2)
\end{verbatim}
Residuals:

<table>
<thead>
<tr>
<th></th>
<th>Min</th>
<th>1Q</th>
<th>Median</th>
<th>3Q</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-2069.89</td>
<td>-433.18</td>
<td>13.67</td>
<td>516.45</td>
<td>1813.75</td>
</tr>
</tbody>
</table>

Coefficients:

|                  | Estimate | Std. Error | t value | Pr(>|t|) |
|------------------|----------|------------|---------|---------|
| (Intercept)      | 2362.720 | 300.687    | 7.858   | 3.11e-13 *** |
| AGE              | 7.093    | 9.925      | 0.715   | 0.4757  |
| LWT              | 8.860    | 3.791      | 2.337   | 0.0205 * |
| as.factor(SMOKE)1| -267.213 | 105.802    | -2.526  | 0.0124 * |

Signif. codes: 0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1

Residual standard error: 708.8 on 185 degrees of freedom
Multiple R-squared: 0.06988, Adjusted R-squared: 0.05479
F-statistic: 4.633 on 3 and 185 DF, p-value: 0.003781

The results output by `summary()` are presented in the same fashion as for simple linear regression. Parameter estimates are given in the column `Estimate`.

The realizations of Student’s test statistics associated with the hypotheses $H_0 : \beta_i = 0$ and $H_1 : \beta_i \neq 0$ are given in column `t value`; the associated $p$-values are in column `Pr(>|t|)`. Residual standard error gives the estimate of $\sigma$ and the number of associated degrees of freedom $n - p - 1$. The coefficient of determination $r^2$ (Multiple R-squared) and an adjusted version (Adjusted R-squared) are given, as are the realization of Fisher’s global test statistic (F-statistic) and the associated $p$-value.

**Analysis of variance table**

The analysis of variance table is given by function `anova()`:

```r
> anova(model2)
Analysis of Variance Table
Response: BWT
  Df Sum Sq Mean Sq F value Pr(>F)
AGE   1  806927 806927  1.6063 0.20661
LWT   1 2970564 2970564  5.9133 0.01598 *
as.factor(SMOKE) 1 3204339 3204339  6.3787 0.01239 *
Residuals 185 92935223 502353 ---
Signif. codes: 0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
```

Fisher’s global $F$ test is used to test the global joint contribution of all explanatory variables in the model to “explaining” the variations of $Y$. The null hypothesis is $H_0 : \beta_1 = \beta_2 = \ldots = \beta_p = 0$ (under the linear model, the $p$ explanatory variables give no useful information to predict $Y$). The assertion of interest is $H_1 :$ at least one of the coefficients $\beta_j$ ($j = 1, 2, \ldots, p$) is significantly
different from zero (at least one of the explanatory variables is associated with $Y$ after adjusting for the other explanatory variables).

**Interpreting results from study “Weight at birth”**

Given the result of Fisher’s global test ($p$-value = 0.003 781), we can conclude that at least one of the explanatory variables is associated with child weight at birth, after adjusting for the other variables. The individual Student tests indicate that:

- mother weight is linearly associated with child weight, after adjusting for age and smoking status, with risk of error less than 5 % ($p$-value = 0.020 5). At same age and smoking status, an increase of one kilogramme in mother weight corresponds to an increase of 8.860 g of average child weight at birth;
- the age of the mother is not significantly linearly associated with child weight at birth when mother weight and smoking status are already taken into account ($p$-value = 0.206 61);
- weight at birth is significantly lower for a child born to a mother who smokes, compared to children born to non-smoker mothers of same age and weight, with a risk of error less than 5 % ($p$-value=0.012). At same age and mother weight, child weight at birth is 267.213 g less for a smoker mother than for a non-smoker mother.

We could have got the same conclusions by looking at confidence intervals and checking whether zero lies in the interval. If zero does not lie in the confidence interval, then the variable has a significant contribution in the model, after adjusting for the other variables.

```
> confint(model2)
            2.5 %     97.5 %
(Intercept) 1769.5042   2955.9351
AGE         -12.4868    26.6732
LWT          1.3807     16.3401
as.factor(SMOKE)1 -475.9460   -58.4800
```

### 12.3.3 Confidence and prediction intervals for a new value

Suppose we wish to predict the weight at birth of a child whose mother is 23 years old, weighs 57 kg, and smokes. The function `predict()` gives a prediction, a prediction interval, and a confidence interval for the mean weight of children whose mothers have these characteristics.
12.3.4 Testing a linear sub-hypothesis: partial Fisher test

Fisher’s partial test is used to test the contribution of a subset of explanatory variables in a model which already includes other explanatory variables. For example, consider the following two models:

- model 1: \( BWT = \beta_0 + \beta_1 LWT + \epsilon \);
- model 2: \( BWT = \beta_0 + \beta_1 LWT + \beta_2 AGE + \beta_3 SMOKE + \epsilon \).

Fisher’s test is used to test the joint contribution of variables \( AGE \) and \( SMOKE \) in model 2. The hypotheses of the test are: \( H_0 : \beta_2 = \beta_3 = 0 \) and \( H_1 : \) at least one of the coefficients \( \beta_2 \) or \( \beta_3 \) is non-zero. The following instructions are used for this test:

```
> anova(model1, model2)
 Analysis of Variance Table
Model 1: BWT ~ LWT
Model 2: BWT ~ AGE + LWT + as.factor(SMOKE)
   Res.Df RSS Df Sum of Sq  F    Pr(>F)
1     187 96468171
2     185 92935223  2   3532949 3.5164 0.03171 *
---
Signif. codes: 0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
```

The \( p \)-value of the test (\( Pr(F) = 0.03171 \)) indicates that at least one of the two variables \( AGE \) or \( SMOKE \) gives extra information to predict child weight at birth, when mother weight has already been taken into account.

When comparing two nested models which only differ by one variable, Fisher’s partial test is equivalent to the individual Student test.

```
> model3 <- lm(BWT ~ LWT + SMOKE)
> anova(model3, model2)
 Analysis of Variance Table
Model 1: BWT ~ LWT + SMOKE
Model 2: BWT ~ AGE + LWT + as.factor(SMOKE)
   Res.Df RSS Df Sum of Sq  F    Pr(>F)
1     186 93191828
2     185 92935223  1   256606 0.5108 0.4757
```
We get the same \( p \)-value as in the individual Student test associated with variable \( \text{AGE} \) in model 2.

### 12.3.5 Qualitative variables with more than two modalities

Binary explanatory variables are not an issue, as shown in the connecting thread example with variable \( \text{SMOKE} \). Using such a variable in a regression model boils down to comparing the mean of the response variable \( Y \) in the two groups defined by the binary qualitative variable. This comparison is said to be adjusted on the other explanatory variables, meaning that we estimate the conditional mean of \( Y \), for fixed values of all the explanatory variables but \( \text{SMOKE} \).

However, for a qualitative variable with more than two modalities, we need to introduce **dummy variables** to compare the mean of \( Y \) in the groups defined by the modalities of the qualitative explanatory variable. A dummy variable for a group or modality is a variable that takes the value 1 in the group and 0 in all other groups.

**Connecting thread example:** Child weight at birth as a function of mother weight and race.

Variable \( \text{RACE} \) is coded with three modalities: 1 for white, 2 for black and 3 for other. In this example, we can therefore define three dummy variables \( \text{RACE1} \), \( \text{RACE2} \) and \( \text{RACE3} \).

<table>
<thead>
<tr>
<th>Categories</th>
<th>( \text{RACE1} )</th>
<th>( \text{RACE2} )</th>
<th>( \text{RACE3} )</th>
</tr>
</thead>
<tbody>
<tr>

<td>3</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

\[
\text{BWT} = \mathbf{X}\beta + \epsilon = \beta_0 \mathbf{1} + \beta_1 \text{LWT} + \beta_2 \text{RACE1} + \beta_3 \text{RACE2} + \beta_4 \text{RACE3} + \epsilon, \quad (12.1)
\]

If we try to fit the following model

\[
\text{BWT} = \mathbf{X}\beta + \epsilon
\]

a problem will occur, as can be seen in the output below:

```r
> summary(lm(BWT ~ LWT + RACE1 + RACE2 + RACE3))
Call:
  lm(formula = BWT ~ LWT + RACE1 + RACE2 + RACE3)
Residuals:
   Min      1Q  Median      3Q     Max

| RACE3      | NA       | NA         | NA      | NA       |

---

Signif. codes:  0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
Residual standard error: 702.7 on 185 degrees of freedom
Multiple R-squared: 0.08578, Adjusted R-squared: 0.07095
F-statistic: 5.786 on 3 and 185 DF,  p-value: 0.0008399

This comes from the fact that the design matrix $X$ is not of full rank:

```
> head(model.matrix(summary(lm(BWT~LWT+RACE1+RACE2+RACE3)))) # First rows of the design matrix.
          (Intercept) LWT    RACE1 RACE2 RACE3
1         1  82.55380      0     1     0
2         1  70.30681      0     0     1
3         1  47.62719      1     0     0
4         1  48.98797      1     0     0
5         1  48.53438      1     0     0
6         1  56.24545      0     0     1
```

Indeed, the sum of the last three columns gives the first column: the model is called non-identifiable. The least squares estimator of $\beta$ is then no more unique (even if predictions based on any least squares estimator of $\beta$ will be unique).

```
> mpinv(model.matrix(summary(lm(BWT~LWT+RACE1+RACE2+RACE3))))%*%as.matrix(BWT)
          [,1]
[1,]   1692.46453
[2,]    10.26709
[3,]    796.29883
[4,]    343.53360
[5,]    552.63210
```

But the trouble is that it is difficult to interpret the coefficients of this vector since non-controllable linear constraints on its components were used (in the sense that two of them are expressed in terms of all other).

We can see that the model (12.1) can be rewritten as:
\[
BWT = \beta_0 + \beta_1 LWT + \beta_2 \text{RACE2} + \beta_3 \text{RACE3} + \epsilon
\]
\[
= \beta_0 + \beta_1 LWT + \beta_2 (1 - \text{RACE2} - \text{RACE3}) + \beta_3 \text{RACE2} + \beta_4 \text{RACE3} + \epsilon
\]
\[
= (\hat{\beta}_0 + \beta_2) + \beta_1 LWT + (\beta_3 - \beta_2) \text{RACE2} + (\beta_4 - \beta_2) \text{RACE3} + \epsilon.
\]

In this latter form, the model is now identifiable ($\gamma_i$’s can be estimated). This is easily verified on the following output:

```r
> summary(lm(BWT~LWT+RACE2+RACE3))$coeff

Estimate Std. Error t value Pr(>|t|)
(Intercept) 2488.76336 241.863663 10.289943 6.348821e-20
LWT 10.26709 3.856339 2.662393 8.442125e-03
RACE2 -452.76523 157.481809 -2.875032 4.513529e-03
RACE3 -243.66673 113.825910 -2.140697 3.360769e-02
```

This consists in taking as a reference the group \text{RACE} = 1 (white race), i.e. to consider the linear regression model with only the dummy variables for the other groups (\text{RACE2}, \text{RACE3}).

To fit a model with qualitative covariates, you can use the function \textbf{factor()} in instruction \texttt{lm()}, as can be seen below:

```r
> model4 <- lm(BWT~LWT+factor(RACE))
> summary(model4)$coeff

Estimate Std. Error t value Pr(>|t|)
(Intercept) 2488.76336 241.863663 10.289943 6.348821e-20
LWT 10.26709 3.856339 2.662393 8.442125e-03
factor(RACE)2 -452.76523 157.481809 -2.875032 4.513529e-03
factor(RACE)3 -243.66673 113.825910 -2.140697 3.360769e-02
```

Note that in this output, \texttt{R} used as reference the group \text{RACE} = 1.

In this context, the estimation $\gamma_2 = \beta_3 - \beta_2 = -452.765$ g represents the difference of child birth weight between black mothers (\text{RACE}=2) and white mothers (reference group), and this result is significantly different from zero ($p$-value=0.004 51) in a model adjusted for mother weight. Similarly, the difference in average weight at birth between group \text{RACE} = 3 and the reference group is $\beta_4 - \beta_2 = -243.667$ g and is significantly different from zero ($p$-value=0.033 61), adjusting for mother weight.

\begin{itemize}
  \item It is possible to change the reference class using the function \texttt{relevel()}.  
\end{itemize}

```r
> summary(lm(BWT~LWT+relevel(factor(RACE),ref=3)))$coeff

Estimate Std. Error t value Pr(>|t|)
(Intercept) 2245.09663 226.805111 9.898792 8.296639e-19
LWT 10.26709 3.856339 2.662393 8.442125e-03
```

\begin{itemize}
  \item Note
\end{itemize}

It is possible to change the reference class using the function \texttt{relevel()}.
To test the global contribution of variable RACE, use a partial Fisher test, as described in the previous section.

```r
> anova(model1, model4)
```

Warning

To resume, never add to the model the dummy variable for the reference group. For a qualitative variable with p modalities, only use p - 1 dummy variables.

12.3.6 Interaction between variables

We say that there is interaction between two explanatory variables $X_1$ and $X_2$ if the association between one of the variables and the response variable $Y$ is not the same depending on the values of the other variable. This corresponds to the notion of effect modification in epidemiology.

Suppose we are interested in the association between $X_1$ and $Y$, and we wish to know whether the effect of $X_1$ on $Y$ is different depending on the values of $X_2$. We simply need to include in the model the variables $X_1$ and $X_2$ as well as a third variable $X_3$ defined as the product of $X_1$ and $X_2$: $X_3 = X_1 \times X_2$ (called the interaction term between $X_1$ and $X_2$). To make things clearer, suppose we wish to determine whether the effect of quantitative variable $X_1$ is modified by binary (0/1) variable $X_2$. We then consider the model:

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_1 \times X_2 + \epsilon.$$  

In group $X_2 = 0$, the model is: $Y = \beta_0 + \beta_1 X_1 + \epsilon$ and the effect of $X_1$ is measured by $\beta_1$. In group $X_2 = 1$, the model is $Y = (\beta_0 + \beta_2) + (\beta_1 + \beta_3) X_1 + \epsilon$ and the effect
of $X_1$ is measured by $\beta_1 + \beta_3$.

There is interaction between $X_1$ and $X_2$ (or modification of the effect of $X_1$ by $X_2$) if the effect of $X_1$ is different in groups $X_2 = 0$ and $X_2 = 1$, i.e. if $\beta_3 \neq 0$. We therefore need to perform an individual Student test on $\beta_3$ ($\mathcal{H}_0 : \beta_3 = 0$ versus $\mathcal{H}_1 : \beta_3 \neq 0$). If we accept $\mathcal{H}_1$, we keep the interaction term in the model: there is modification of effect.

**Connecting thread example:** Modification of the effect of mother age on child weight at birth by mother’s smoking status.

We first consider the model

$$BWT = \beta_0 + \beta_1 AGE + \beta_2 SMOKE + \epsilon.$$  

```r
> model5 <- lm(BWT ~ AGE + SMOKE)
```

This model assumes that the effect of $AGE$ is the same for smoker and non-smoker mothers. We can propose a more flexible model, allowing for different effects in the two groups $SMOKE=0$ and $SMOKE=1$:

$$BWT = \beta_0 + \beta_1 AGE + \beta_2 SMOKE + \beta_3 AGE \times SMOKE + \epsilon$$

```r
> model6 <- lm(BWT ~ AGE + SMOKE + AGE:SMOKE)
```

**Tip**

To introduce an interaction term between the two variables $X_1$ and $X_2$ in a linear model, simply type $X_1:X_2$. Note that $X_1*X_2$ in a formula corresponds to $X_1+X_2+X_1:X_2$. The previous call could have been replaced with:

```r
> model6 <- lm(BWT ~ AGE*SMOKE)
```

The difference between the two models can be visualized on the next two plots. The first plot shows two parallel lines; the slope represents the effect of $AGE$ on $BWT$, which is the same for smokers and non-smokers.

```r
> co <- coef(model5); a0 <- co[1] ; a1 <- co[1]+co[3]
> b <- co[2]
> fSMOKE <- as.factor(SMOKE)
> plot(BWT ~ AGE, xlab="AGE in years", ylab="Weight at birth (g)", main=expression(BWT"="\beta_0+\beta_1*AGE+\beta_2*SMOKE+\epsilon),
+  col = c('blue','red')[fSMOKE], pch=c(1,18)[fSMOKE])
> abline(a=a0,b,col="blue") ; abline(a=a1,b,col="red")
```
12.3 Multiple linear regression

\[ BWT = \beta_0 + \beta_1 \text{AGE} + \beta_2 \text{SMOKE} + \epsilon \]

Fig. 12.7: Effect of age on BWT in a model without interaction.

The next plot shows two different slopes, illustrating the notion of interaction.

```r
> co <- coef(model6); a0 <- co[1]; a1 <- co[1]+co[3]
> plot(BWT~AGE, xlab="AGE in years", ylab="Weight at birth (g)",
+      main=expression(BWT~"=\beta_0+\beta_1\text{AGE}+\beta_2\text{SMOKE}+
+                       \epsilon"))
> points(AGE[SMOKE==1],BWT[SMOKE==1],col="red",pch=18)
> points(AGE[SMOKE==0],BWT[SMOKE==0],col="blue")
> abline(a=a0,b0,col="blue") ; abline(a=a1,b1,col="red")
```
We can test the significance of the interaction term by analysing the results of model 6.

```r
> summary(model6)
Call:
  lm(formula = BWT ~ AGE * SMOKE)
Residuals:
  Min 1Q Median 3Q Max
-2187.8 -456.6 52.8 526.6 1522.2
Coefficients:
            Estimate Std. Error t value Pr(>|t|)
(Intercept) 2408.38      292.24  8.241  3.05e-14 ***
AGE          27.60       12.15  2.271   0.0243 *
SMOKE        795.38      484.42  1.642   0.1023
AGE:SMOKE   -46.36       20.45 -2.267   0.0245 *
---
Signif. codes:  0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
Residual standard error: 709.4 on 185 degrees of freedom
Multiple R-squared: 0.0683, Adjusted R-squared: 0.05319
F-statistic: 4.521 on 3 and 185 DF,  p-value: 0.004378
```

The coefficient $\beta_3$ is significantly different from zero ($p$-value=0.024). We therefore conclude that the effect of mother age on child weight at birth is not the same...
depending on the smoking status of the mother. The results on association between mother age and child weight at birth must therefore be presented separately for the smoker and non-smoker groups.

For completeness sake, for non-smoker mothers, the effect of \( \text{AGE} \) is significant (\( p \)-value=0.0243). The mean child weight at birth increases with mother age, by 27.60 g (\( \hat{\beta}_1 \)) for one extra year for the mother. A confidence interval is given by:

\[
> \text{confint(model6)}[2,]
\]

2.5 % 97.5 %
3.628108 51.573048

For smoker mothers, the mean child weight at birth decreases with mother age, by 18.762 g (\( \hat{\beta}_1 + \hat{\beta}_3 \)) for one extra year for the mother. To know whether this result is significant, we calculate the confidence interval for \( \beta_1 + \beta_3 \). A clever way of doing this is to create a new variable \( \text{SMOKE1} \) which reverses the coding of \( \text{SMOKE} \), then to launch the instructions

\[
> \text{SMOKE1} \leftarrow 1-\text{SMOKE}
> \text{confint(lm(BWT} \sim \text{AGE+SMOKE1+AGE:SMOKE1})[2,]
\]

2.5 % 97.5 %
-51.21423 13.68941

The value 0 lies in the confidence interval, thus the effect of \( \text{AGE} \) on \( \text{BWT} \) is not significant for smoker mothers.

### 12.3.7 Issues with collinearity

When several explanatory variables give the same kind of information, several phenomena can occur:

- disruption of estimate quality (very large variance);
- contradictory values of coefficients (opposite signs);
- non-significant coefficients.

These are **collinearity issues**.

The criterion used to quantify collinearity of explanatory variables is the variance inflation factor VIF: \( \frac{1}{1-r_j^2} \) where \( r_j^2 \) is the multiple coefficient of determination when we regress the \( j \)th explanatory variable \( x_j \) on the set of other regressors.

The VIF plays an essential role in estimator variance since \( \text{Var}(\hat{\beta}_j|X = X) = \frac{s_j^2}{\hat{\beta}_j} \times \frac{1}{1-r_j^2} \) where \( s_j^2 = \frac{1}{n} \sum_{i=1}^{n} (x_{ij} - \bar{x}_j)^2 \) is the variance of the sample \( x_j \). The more \( x_j \) is collinear to the other regressors, the closer \( r_j^2 \) is to 1, hence the higher the term \( \frac{1}{1-r_j^2} \); the variance of the estimator \( \hat{\beta}_j \) is then very high. Conversely, the closer \( r_j^2 \) is to 0, the closer the associated VIF is to 1 (the minimum). Thus, the more \( x_j \) is “independent” of the other regressors, the less the estimates are disrupted. Collinearity of regressors necessarily has an impact on estimator precision. We say there is strong
collinearity when $VIF_j > 10$ (i.e. $r_j^2 > 0.9$).

The R instruction to compute the VIF is `vif()`, available in package `car`.

We show how to use the function `vif()` in the very simple example of model

$$\mathbb{E}[\text{BWT}|\text{LWT}, \text{AGE}] = \beta_0 + \beta_1 \text{LWT} + \beta_2 \text{AGE}.$$ 

```r
> model7 <- lm(BWT ~ LWT + AGE)
> vif(model7)
         LWT      AGE
  1.033513 1.033513
```

Note

In this case, the VIFs are equal, since there are only two regressors. This is a very simple example: there are only two regressors and we could have analysed this collinearity graphically, but the usefulness of this method is clear when there is a large number of regressors.

### 12.3.8 Variable selection

Amongst the large number of possible explanatory variables, we wish to select those which explain $Y$ the best. This way, we can decrease the number of predictors (giving a parsimonious model) and get good predictive power by eliminating redundant variables which increase the variance inflation factor (VIF).

The greater the number of parameters (large number of explanatory variables), the better the fit to the data ($r^2$ close to 1). As a trade-off, parameter estimation is disrupted (variance of estimators increases) because of collinearity issues.

In this section, we briefly present a few methods for variable selection available in R. They are illustrated on a few variables from data set `BIRTH.WEIGHT`.

We consider the explanatory variables `LWT`, `AGE`, `UI`, `SMOKE`, `HT` and two recoded variables `FTV1` and `PTL1`. We note $\text{FTV1} = 1$ if there was at least one visit to a physician, and $\text{FTV1} = 0$ otherwise. Similarly, we note $\text{PTL1} = 1$ if there is at least one preterm birth in the family history, and $\text{PTL1} = 0$ otherwise.

► **Best subset method**

When the number $p$ of explanatory variables is not too large, we can study all possibilities. One efficient algorithm (see [18] and [19]) can go up to thirty variables: the leaps and bounds method. At fixed $p$, we choose the regression model
with the largest $r^2$. For two regression models with different numbers of explanatory variables, we can choose the one with largest adjusted $r^2_a$.

The relevant R function is `leaps()` available in package `leaps`.

```r
> FVT1 <- FVT; FVT1 <- as.integer(FVT>=1)
> PTL1 <- PTL; PTL1 <- as.integer(PTL>=1)
> matx <- model.matrix(lm(BWT~LWT+AGE+UI+SMOKE+HT+FVT1+PTL1))
> # Equivalent to: matx <- cbind(LWT,AGE,UI,SMOKE,HT,FVT1,PTL1)
> adjr2.leaps <- leaps(matx,BWT,nbest=1,method="adjr2")
> best.model.adjr2 <- adjr2.leaps$which[adjr2.leaps$adjr2==max(adjr2.leaps$adjr2),]
> best.model.adjr2

1 2 3 4 5 6 7
TRUE FALSE TRUE TRUE TRUE FALSE TRUE
```

The best model in the sense of the adjusted $r^2_a$ is thus:

$$BWT = \beta_0 + \beta_1LWT + \beta_2UI + \beta_3SMOKE + \beta_4HT + \beta_5PTL1 + \epsilon.$$ 

**Note**

You can use other selection criteria than the adjusted $r^2_a$ with the argument `method` of function `leaps()`. For example, `method="Cp"` uses Mallows’ $C_p$ criterion [27].

Another interesting function in package `leaps` is `regsubsets()`. For example, with its argument `force.in`, it can be used to specify one or several variables which must be included in all models considered. We give an example using the BIC (Bayesian information criterion) to choose the best model [37]):
> # Force SMOKE to be included:
> best.model.bic <- regsubsets(matx,BWT,nbest=1,force.in=4)
> summary(best.model.bic)$bic # BIC values of best models of
# each size (nbest=1).
> plot(best.model.bic)

![Graph showing BIC values for different models.](image)

Fig. 12.9: Selecting variables with the BIC.

The best model is the one with lowest BIC. The best model, in the sense of the BIC, is:

\[ \text{BWT} = \beta_0 + \beta_1 \text{LWT} + \beta_2 \text{UI} + \beta_3 \text{SMOKE} + \beta_4 \text{HT} + \epsilon. \]

**Note**

Other selection criteria can be used with argument `scale` in function `plot()` applied to an object of class `regsubsets` or using `$rsq`, `$rss`, `$adjr2` and `$cp` (for $r$-squared, residual sum of squares, adjusted $r$-squared,
and Mallows' Cp respectively), instead of $\text{bic}$, with the function `summary()` as shown above.

**Forward selection**

The forward selection method is an iterative method. At each step, it selects the most significant explanatory variable (at level $\alpha$) when we regress Y on all explanatory variables selected at previous steps and the newly chosen variable, as long as the marginal contribution of the new variable is significant.

Watch this method in action with function `add1()` for level $\alpha = 0.05$.

```r
> add1(lm(BWT~1), BWT~LWT+AGE+UI+SMOKE+HT+FVT1+PTL1, test="F")

No further variable is significant. The method thus stops at the model with variables: UI, HT, LWT and SMOKE.

▶ Backward selection

This time, we start with the complete model and at each step, we delete the variable with lowest value of Student’s test statistic (largest p-value) in absolute value, as long as it is not significant (at a specified level $\alpha$).

Watch this method in action with function drop1() for level $\alpha = 0.05$.

The method stops at the model with variables: UI, HT, LWT and SMOKE.

**The stepwise method**

This algorithm is an improvement upon the forward selection method. At each step, it performs Student or Fisher tests, or optimize some criterion, to not add a non-significant variable and possibly delete previously included variables which are no longer significant given the latest included variable. The algorithm stops when no variables can be added or deleted.

We present function `step()` to perform the stepwise method, using at each step a selection procedure based on the AIC criterion [2] (An Information Criterion). One can also use the well known BIC criterion (Bayesian Information Criterion) by means of the `k=log(n)` argument of the `step()` function.

```r

Warning

The data set Birth-weight has been used here only to illustrate how to use R functions for automatic selection, even though the best strategy for this data set would have been to select “by hand”.

Indeed, it should be noted that different methods of automatic selection may not lead to the same choice of variables in the final model. They have the ad-
vantage of being easy to use, and of treating the question of variable selection in a systematic manner. The main drawback is that variables are included or deleted based on purely statistical criteria, without taking into account the aim of the study. This usually leads to a model which may be satisfactory from a statistical point of view, but in which the variables are not the most relevant when it comes to understanding and interpreting the data in the study.

12.3.9 Analysis of residuals

We present here a few elements on analysis of residuals. This method is useful to check the assumptions of the model and to detect possible outliers. For further details, we recommend you read [41].

► Validating model assumptions

We have already mentioned that for simple linear regression, analysis of residuals can be used to check the assumptions of the regression model. We showed two plots to check the assumptions of normally distributed errors and homoscedasticity of errors.

Connecting thread example: Study “Child weight at birth”.

We study the validity of the assumptions for the model

\[
\text{BWT} = \beta_0 + \beta_1 \text{SMOKE} + \beta_2 \text{AGE} + \beta_3 \text{LWT} + \beta_4 \text{RACE}2 + \beta_5 \text{RACE}3 + \beta_6 \text{UI} + \beta_7 \text{HT} + \beta_8 \text{SMOKE} \times \text{AGE} + \epsilon.
\]
> finalmodel<-lm(BWT~SMOKE+AGE+LWT+factor(RACE)+UI+HT+SMOKE:AGE)
> par(mfrow=c(1:2))
> plot(finalmodel,1:2,col.smooth="red")

Fig. 12.10: Checking the assumptions of homoscedasticity (left) and normality (right).
> res <- residuals(finalmodel)
> par(mfrow=c(2,3))
> plot(res ~ SMOKES); plot(res ~ AGES); plot(res ~ LWT)
> plot(res ~ RACE); plot(res ~ UI); plot(res ~ HT)

Fig. 12.11: Residuals as a function of explanatory variables.
It can also be useful to plot the residuals as a function of each explanatory variable, as shown in the above figure. This plot is useful to check whether there is a relationship between the error term and the explanatory variables, which would invalidate the assumption of independence between errors and explanatory variables. This plot is also useful to detect outliers.

### Outliers and influential points

An outlier is a point with a large value of its residual. It is a point which is often distant from the others. It can be visualized on the plot of residuals against predicted values (or against an explanatory variable) as a point very far away. Several kinds of residuals can then be defined:

- **Standardized residuals**
  \[ t_i = \frac{\hat{e}_i}{\hat{\sigma} \sqrt{1 - h_{ii}}} \]
  where \( h_{ii} \) is the “leverage” (defined later on). These residuals are given by function `rstandard()`. Standardized residuals are “mostly” between -2 and 2, but they are dependent;

- **Studentized residuals**
  \[ t'_i = \frac{\hat{e}_i}{\hat{\sigma}_{(-i)} \sqrt{1 - h_{ii}}} = t_i \sqrt{\frac{n - p - 2}{n - p - 1 - t_i^2}} \]
  where \( \hat{\sigma}_{(-i)} \) is the residual estimated without observation \( i \). Studentized residuals are given by function `rstudent()`. An observation is called an outlier when \( |t'_i| > t_{0.975}^{(n-p-2)} \) (where \( t_{0.975}^{(n-p-2)} \) is the 0.975 quantile of a Student distribution with \( n - p - 2 \) degrees of freedom).

```r
> res.stud <- rstudent(finalmodel)  # Calculating studentized residuals.
> threshold.stud <- qt(0.975,189-8-2)  # Calculating the threshold for the Student distribution.
> cond <- res.stud<(-threshold.stud) | res.stud > threshold.stud  # List of individuals who can be considered outliers.
> id.student <- ID[cond]  # ID (identification number) is in first column of dataset.
> val.ajust <- fitted(finalmodel)
> plot(res.stud˜val.ajust,xlab="Fitted values", + ylab="Studentized residuals",pch=20)
> abline(h=c(-threshold.stud,threshold.stud))
```
Another way of studying outliers is the notion of “leverage points”. The leverage for observation \( i \) (noted \( h_{ii} \)) is the value on the diagonal of matrix \( \mathbf{H} = \mathbf{X}(\mathbf{X}^T\mathbf{X})^{-1}\mathbf{X}^T \) (the hat matrix). This measure is mostly used for the variance of residuals: \( \text{Var}(\hat{\epsilon}_i) = \sigma^2(1 - h_{ii}) \). A leverage above \( 2(p + 1)/n \) can be considered too large. Large \( h_{ii} \) indicates that the \( i \)th observation is far from the centre of gravity.

The \( h_{ii} \), stored in vector \text{leverage}, are given by:

\[
> \text{leverage} <- \text{hatvalues(finalmodel)}
\]

Fig. 12.12: Visualizing outliers: studentized residuals against fitted values.
To detect leverage points, you can type:

```r
> threshold.leverage <- 2*(8+1)/189
> outl.leverage <- ID[leverage>threshold.leverage]
> # List of individuals with large leverage:
> outl.leverage
[15]  20  28  75  83  84
```

Other diagnostics can be used to inspect outliers and check their influence on the regression model:

- **Cook’s distance.** It is used to measure the influence of observation \( i \) on the estimation of the regression parameters. It is defined as:

\[
C_i \equiv \sum_{j=1}^{n} \left( \frac{\hat{y}_j - \hat{y}_j^{(-i)}}{\hat{\sigma}^2} \right)^2
= \left( \frac{1}{p+1} \right) \left( \frac{h_{ii}}{1-h_{ii}} \right) \hat{\epsilon}_i^2
= \left( \frac{1}{p+1} \right) \left( \frac{h_{ii}}{1-h_{ii}} \right) \frac{\hat{\sigma}^2}{\hat{\epsilon}_i^2}
= \left( \frac{1}{p+1} \right) \left( \frac{h_{ii}}{1-h_{ii}} \right) \frac{\hat{\epsilon}_i^2}{\hat{\epsilon}_j^2}
\]

where \( \hat{y}_j^{(-i)} \) is the prediction at point \( x_j = (1, x_{j1}, \ldots, x_{jp})^T \) given by the model estimated without the \( i \)th observation.

A large value of \( C_i \) indicates that the \( i \)th observation is influential (1 is sometimes used as the threshold). Deleting this observation can lead to big modifications in the regression equation. The function to calculate Cook’s distance is `cooks.distance()`.

Here is a graphical representation:
> plot(cooks.distance(finalmodel), type="h")
> # Or plot(finalmodel, 4)

Fig. 12.13: Visualizing influential observations: Cook’s distance.

According to Cook’s distance, no value seems globally influential.

- **Welsch-Kuh distance or Dffits.** It is defined as:

  \[ D_{\text{ffits}} = \frac{\hat{y}_i - \hat{y}_{i(-i)}^{(-i)}}{\partial \hat{y}_{(-i)} / \partial y_i \sqrt{h_{ii}}} = t' \sqrt{\frac{h_{ii}}{1 - h_{ii}}}. \]

  Large \(|D_{\text{ffits}}|\) indicates that observation \(i\) has an influence on the estimate \(\hat{y}_i\), which means that observation is influential on the regression results. In prac-
an observation is considered influential if $|D_{\text{dffits}}| \geq 2 \sqrt{\frac{p+1}{n}}$.

The R function to calculate the Dffits is `dffits()`.

```r
threshold.dffit <- 2*sqrt((8+1)/189)
ID[abs(dffits(finalmodel))>=threshold.dffit]
```

- **The Dfbetas measure.** It is defined as:
  
  $$D_{\text{fbetas}}_{ji} = \frac{\hat{\beta}_j - \hat{\beta}_j^{(-i)}}{\hat{\sigma}_{j} \sqrt{(\hat{\beta}^T \hat{\beta})_{i+1,j+1}}},$$

  where $\hat{\beta}_j^{(-i)}$ is the estimate of $\beta_j$ obtained without using the $i$th observation. This quantity measures the influence of observation $i$ on the estimate of the $j$th coefficient. For small or medium-size datasets, a value larger than 1 is suspect. For large datasets, observation $i$ is suspect if $|D_{\text{fbetas}}_{ji}| > 2/\sqrt{n}$ for at least one $j$.

  The R function to calculate the Dfbetas is `dfbetas()`.

```r
threshold.dfbetas <- 1
ID[apply(abs(dfbetas(finalmodel))>threshold.dfbetas, + FUN=any,MARGIN=1)]
integer(0)
```

Here, no value seems suspect.

- **Covariance ratio.** It is defined, for the $i$th observation, as the ratio of the determinant of the estimated matrix of variances-covariances of $\hat{\beta}_{(-i)}$ (estimator of $\beta$ obtained without using the $i$th observation) by the determinant of the estimated matrix of variances-covariances of $\hat{\beta}$ (estimator of $\beta$):

  $$\frac{\det[\text{Var}(\hat{\beta}_{(-i)})]}{\det[\text{Var}(\hat{\beta})]}.$$ 

  If the ratio is near 1, the $i$th observation does not significantly influence the covariance matrix.

```r
max(abs(covratio(finalmodel)-1))
[1] 0.2897528
```
For further details on these diagnostics, you can read [41], [4] or [11].

12.3.10 Polynomial regression

In a polynomial model, the relationship between the explained variable $Y$ and an explanatory variable $X$ is represented in a non-linear fashion, such as:

$$ Y = \beta_0 + \beta_1 X + \beta_2 X^2 + \ldots + \beta_p X^p + \epsilon. $$

This model is a multiple regression model with $p$ regressors: the powers of the explanatory variable.

To perform regression in a polynomial model, you simply need to correctly specify the formula associated with the model in the function `lm()`. Two R functions are useful: `I()` and `poly()`. The next table gives a few examples of formulae for polynomial models.

<table>
<thead>
<tr>
<th>Model</th>
<th>R formula</th>

12.3 Multiple linear regression

**Memorandum**

- `lm()`: perform linear regression
- `summary(lm())`: results of the linear model
- `confint()`: confidence interval for regression parameters
- `predict()`: prediction of new values
- `residuals()`: recover residuals of a linear model
- `plot(lm())`: plots for model validation
- `pairs()`: scatter plot
- `anova(lm())`: analysis of variance table of a linear model
- `X1:X2`: interaction term
- `rstandard()`: standardized residuals
- `rstudent()`: studentized residuals
- `vif()`: calculation of VIF
- `cooks.distance()`: Cook’s distance
- `dffits()`: Welsh-Kuh distance
- `dfbetas()`: Dfbetas measure
- `step()`: stepwise method with AIC
- `regsubsets()`: selection by exhaustive search

**Exercises**

12.1- Give the instruction to fit the model $Y = \beta_0 + \beta_1 X_1 + \epsilon$.
12.2- Give the instruction to fit the model $Y = \beta_1 X_1 + \epsilon$.
12.3- Give the instruction to fit the model $Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \epsilon$.
12.4- Give the instruction to fit the model $Y = \beta_0 + \beta_1 X_1 \times \beta_2 X_2 + \beta_3 X_1 + \beta 4X_2 + \epsilon$.
12.5- Give the instruction to fit the model $Y = \beta_0 + \beta_1 X_1 + \beta_2 X_1^2 + \beta_3 X_1^3 + \epsilon$.
12.6- Which instruction performs a partial Fisher test?
12.7- Which function recovers the residuals of a model?
12.8- Which function gives the estimates of a regression model?
12.9- Let $Z$ be a qualitative variable. Which function should you use to fit a regression model with $Z$ as the explanatory variable?
12.10- Give the instruction to fit the polynomial model $Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2^2 + \beta_3 X_3^3 + \epsilon$.
12.11- Which function performs forward selection?
12.12- Which function performs backward selection?
A- Study of simple linear regression

- Study of synthetic data

12.1- Simulate a dataset \((x_i, y_i), \ i = 1, \ldots, n\) from a simple linear regression model. To this end:
  - choose the true parameters \(\beta_0\) and \(\beta_1\), as well as \(\sigma > 0\);
  - simulate the vector of errors \(e\) of size \(n\) from a normal distribution \(N(0, \sigma^2)\);
  - simulate the vector of values of the explanatory variable \(x\) of size \(n\) from a uniform distribution over \([0, t]\) where \(t\) is a positive real number of your choosing;
  - construct the vector of values of the explained variable \(y\) of size \(n\) from the linear regression model.

12.2- Plot the \(n\) points \((x_i, y_i)\).

12.3- Give an estimate of the regression parameters and of the error variance.

12.4- Analyse the residuals to validate the model:
  - plot the residuals against the fitted values;
  - plot the fitted values against the observed values;
  - draw a plot to check the normality of residuals.

12.5- Change the values of \(n\) and \(\sigma\) to understand the consequences on the precision of the regression parameter estimates (in terms of variance).

- Study of intima-media

In the “Intima-media” study, we wish to study the relationship between intima-media thickness and age.

12.1- Download the intima-media data file.

12.2- Plot variable measure as a function of variable AGE. Describe this scatter plot.

12.3- Is there a link between these variables? Explain how to measure the severity of the link.

12.4- We now wish to fit a regression line on this scatter plot:
  - propose a regression model and estimate the parameters of the model;
  - draw the regression line over the scatter plot.

12.5- Analyse the residuals to validate the model.

12.6- Give a prediction interval for intima-media thickness for a 33 years old person.
12.7- Give a confidence interval for the average intima-media thickness of 33 years old people.

12.8- Propose a model to increase the predictive power of intima-media thickness, using only AGE as an explanatory variable.

### B- Study of multiple linear regression

- **Study of intima-media**

  In the previous practical, we looked at the relationship between intima-media thickness and age. We now wish to fit a regression model on all variables which may explain variations in intima-media thickness. The study will rely on the following variables: AGE, SPORT, alcohol, packyear and the variable BMI which you must create from variables height, weight.

  We are mostly interested in tobacco, through the variable packyear as main exposure factor. We therefore decide to keep this variable in the model even if it is not significant.

12.1- Draw scatter plots of all pairs of variables (explained and explanatory). Do you suspect any issues with collinearity?

12.2- Perform a univariate analysis of intima-media thickness of each explanatory variable.

12.3- We only keep the explanatory variables associated with significance level \( p < 0.25 \) in the univariate analysis. One by one, test all possible interactions between the selected explanatory variables and the main exposure variable packyear.

12.4- Estimate and analyse the model with all variables which were declared significant in the univariate analyses (\( \alpha = 25 \% \)) and all interaction terms significant at the 10 % level.

12.5- Are the interaction terms still significant? Remove interaction terms which are no longer significant at the 10 % level.

12.6- Starting with the model from the previous question, remove one by one all variables which are not significant at the 5 % level, making sure that the removals do not make a big difference on the estimate of the coefficient associated with tobacco status.

12.7- Interpret the final model.

- **Study of unemployment rates**

  This practical studies unemployment rates from 1960 to 1993. The dataset unemployment is made of \( n = 34 \) yearly observations (from 1960 to 1993). Here is a description of the variables:

- **year**: year;
- **unemp**: unemployment rate;
• **gdprate**: rate of variation of Gross domestic product (GDP), representing economic growth;
• **govspend**: ratio of government spending and GDP, representing the degree of intervention of the state in the economy;
• **taxb**: tax burden, to see whether taxation of businesses has an impact on hiring policy, and hence on unemployment rates;
• **salav**: ratio of salaries to added value, to know the influence of cost at hiring;
• **infl**: inflation rate, to verify the inverse relationship between unemployment and inflation, defined in the Philips curve.

12.1- We consider a linear model explaining variable **unemp** as a function of variable **gdprate** only. Download the dataset [http://www.biostatisticien.eu/springeR/unemployment.RData](http://www.biostatisticien.eu/springeR/unemployment.RData). Perform a complete analysis of the underlying simple linear regression model.

12.2- We consider a multiple linear model explaining variable **unemp** as a function of all explanatory variables in the dataset (except variable **year**). Give the correlation matrix of all these variables.

12.3- Draw scatter plots of all pairs of variables.

12.4- Which explanatory variables seem to make the biggest contribution? Do you suspect collinearity between regressors?

12.5- Present the results of the multiple linear regression model with explanatory variables.

12.6- Calculate the **VIF** associated with each explanatory variable.

12.7- Perform backward variable selection with threshold \( \alpha = 0.2 \).

12.8- Present the final model.

12.9- Suppose we do not know the value of **unemp** in 1993. Can you predict its value, and calculate a 95 % prediction interval?

12.10- What is the observed value of **unemp** in 1993? Is this surprising?

**C- Study of polynomial regression**

• **Study of synthetic data**

12.1- Simulate a sample of size \( n = 100 \) from the following model:

\[
Y = X + 2X^2 + 3.5X^3 - 2.3X^4 + \epsilon
\]

where \( X \) follows a uniform distribution over \([-2, +2]\) and \( \epsilon \) follows a \( N(0, 1) \) distribution.

12.2- Draw the scatter plot and the simulated polynomial line.

12.3- Fit a simple linear regression model. Remember to analyse the residuals.

12.4- Fit a polynomial regression, using a polynomial of degree 4. Draw the estimated model over the scatter plot.
• Fitting a scatter plot with a polynomial

Suppose you are asked to propose a model to predict a variable $Y$ given an explanatory variable $X$. You are given a sample of size $n$.

12.2- Draw a scatter plot of variable $Y$ as a function of variable $X$.
12.3- Is there a linear relationship between these two variables? Fit a regression line on the previous plot.
12.4- Perform polynomial regression to fit the data better.
12.5- Draw the estimated polynomial over the scatter plot. Draw the confidence curve for the mean of $Y$ for $X \in [-3.5, 3.5]$. Add the prediction interval of the model for $X \in [-3.5, 3.5]$. 

Chapter 13
Elementary analysis of variance

Prerequisites and goals of this chapter

- Read Chapter 12.
- This chapter describes the various R commands to perform analysis of variance. We present the standard cases of analysis of variance with 1 factor and 2 factors with or without interaction. We also introduce repeated measures analysis of variance.

SECTION 13.1

Analysis of variance with one factor

13.1.1 Aims, data and model

- **Aim:** Analysis of variance (ANOVA) is a method to study the modification of the mean $\mu$ of a phenomenon under study $Y$ (quantitative variable) under the influence of one or several qualitative experimental factors (treatments). In the case where the mean is only influenced by one factor (noted $X$), it is analysis of variance with one factor or one-way ANOVA. A factor is often a qualitative variable with a small number of modalities. The number of modalities (or levels) of factor $X$ is noted $I$. We assume that $Y$ follows a normal distribution $\mathcal{N}(\mu_i, \sigma^2)$ in each subpopulation $i$ defined by the modalities of $X$. The aim is to test whether these $I$ populations have equal means, *i.e.* to test the null hypothesis

$$\mathcal{H}_0 : \mu_1 = \mu_2 = \cdots = \mu_I$$
against the assertion of interest

\[ \mathcal{H}_1 : \exists i \neq i' / \mu_i \neq \mu_{i'} ("\text{there are at least two different means}).\]

**Data:** For each sub-population \( i \) (or modality \( i \) of \( X \), or group \( i \)), we are given a sample of \( n_i \) observations from the quantitative variable \( Y \):

\[ y_{i,1}, y_{i,2}, \ldots, y_{i,n_i}. \]

The model is written

\[ Y_{ik} = \mu_i + \epsilon_{ik}, \quad \text{for } k = 1, \ldots, n_i \text{ and } i = 1, \ldots, I \]

where the errors \( \epsilon_{ik} \) are independent random variables following the distribution \( \mathcal{N}(0, \sigma^2) \). We can also write \( \mu_i \) as: \( \mu_i = \mu + \alpha_i \), for \( i = 1, \ldots, I \). In this setting, \( \mu \) is called the mean effect of the factor and \( \alpha_i = \mu_i - \mu \) is called the differential effect for level \( i \) of the factor. The above model can therefore also be written as:

\[ Y_{ik} = \mu + \alpha_i + \epsilon_{ik}, \quad \text{for } k = 1, \ldots, n_i \text{ and } i = 1, \ldots, I. \]

This model is not identifiable (which means that some parameters cannot be estimated). We therefore have to impose a (linear) constraint to make it identifiable, for example \( \sum_{i=1}^{I} \alpha_i = 0 \), which corresponds to taking the mean effect \( \mu \) as the reference.

**Warning**

By default, \( \text{R} \) imposes the constraint \( \alpha_1 = 0 \). All comparisons are then made relatively to \( \mu_1 \). The reference class is level 1 of the factor.

**See also**

The concept of a reference group has already been explained on page 478 of Chapter 12.

### 13.1.2 Example and graphical inspection

**Example of use:** Fever buttons.

Five treatments \((T_1, \ldots, T_5)\) against fever buttons, including one placebo, were randomly assigned to thirty patients (six patients per treatment group). For each patient, the time (in days) between the apparition of the buttons and complete scarring was measured.
The aim here is to compare the theoretical means of scarring times; these times were observed on five independent samples (treatment groups.)

**Graphical inspection:** We first perform a brief descriptive analysis of the data, to see whether any probable patterns emerge.

```r
> X <- data.frame(Placebo = c(5, 8, 7, 7, 10, 8), T2 = c(4, 6, 6, 3, 5, 6),
  + T3 = c(6, 4, 4, 5, 4, 3), T4 = c(7, 4, 6, 6, 3, 5), T5 = c(9, 3, 5, 7, 7, 6))
> times <- stack(X)$values # stack() is used to stack vectors.
> treatment <- stack(X)$ind
> tapply(times, treatment, summary)

$Placebo
Min. 1st Qu. Median Mean 3rd Qu. Max.
5.0 7.0 7.5 7.5 8.0 10.0

$T2
Min. 1st Qu. Median Mean 3rd Qu. Max.
3.0 4.25 5.50 5.00 6.00 6.00

$T3
Min. 1st Qu. Median Mean 3rd Qu. Max.
3.000 4.000 4.000 4.333 4.750 6.000

$T4
Min. 1st Qu. Median Mean 3rd Qu. Max.
3.000 4.250 5.500 5.167 6.000 7.000

$T5
Min. 1st Qu. Median Mean 3rd Qu. Max.
3.000 5.250 6.500 6.167 7.000 9.000
```
13.1.3 ANOVA table and parameter estimation

R instruction for the ANOVA table: Use the function `aov()`. As for regression models, ANOVA works with R formulae. You therefore have to specify the model.

```r
> my.aov <- aov(times ~ treatment)
> summary(my.aov)

             Df Sum Sq Mean Sq F value Pr(>F)
 treatment   4 36.467  9.1167  3.896  0.01359 *
 Residuals 25 58.500  2.3400
---
Signif. codes: 0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 . ‘.’ 0.1 ‘ ’ 1
```

If it has not already been done, remember to declare your factor variable (in this case, the variable `treatment`) as an R object of type `factor`, using the function `factor()`.

```r
> class(treatment)
[1] "factor"
```
13.1 Analysis of variance with one factor

ANOVA is in fact a linear model, so note that it is also possible to perform analysis of variance of the underlying linear model:

```r
> model <- lm(times ~ treatment)
> anova(model)
Analysis of Variance Table
Response: times
 Df Sum Sq Mean Sq F value Pr(>F)
 treatment 4 36.467 9.1167 3.896 0.01359 *
 Residuals 25 58.500 2.3400
---
Signif. codes: 0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
```

Note that you can also use the function `Anova()` from package `car`. This function is more complete and can handle more complex data.

The analysis of variance table outputs the result of Fisher’s test for the hypotheses: $\mathcal{H}_0 : \mu_1 = \mu_2 = \cdots = \mu_I$ and $\mathcal{H}_1 : \exists i \neq i' / \mu_i \neq \mu_{i'}$ (“there are at least two different means”). The $p$-value=0.013 allows us to conclude that the effects of at least two treatments are different, although we do not know which ones.

Tip

Estimating the parameters of the model: Estimates are given by the function `summary()` for model `lm(times ~ treatment)`. Recall that R imposes the constraint $\alpha_1 = 0$.

```r
> summary(model)
Call:
 lm(formula = times ~ treatment)
Residuals:
 Min 1Q Median 3Q Max
-3.1667 -0.8750 -0.0833 0.8333 2.8333
Coefficients:
 Estimate Std. Error t value Pr(>|t|)
(Intercept) 7.5000 0.6245 12.010 7.06e-12 ***
treatmentT2 -2.5000 0.8832 -2.831 0.00903 **
treatmentT3 -3.1667 0.8832 -3.586 0.00142 **
treatmentT4 -2.3333 0.8832 -2.642 0.01401 *
treatmentT5 -1.3333 0.8832 -1.510 0.14366
---
Signif. codes: 0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
Residual standard error: 1.53 on 25 degrees of freedom
Multiple R-squared: 0.384, Adjusted R-squared: 0.2854
F-statistic: 3.896 on 4 and 25 DF, p-value: 0.01359
```

The intercept corresponds to the estimate of the mean time for the placebo (treatment 1 is the reference). The estimate associated with variable T2 corresponds to the differential effect between treatment T2 and the placebo. The same goes for the other variables. The assertions of interest and the two-
by-two Student tests performed in this model (with constraint $\alpha_1 = 0$) are summed up in the following table:

<table>
<thead>
<tr>
<th>$H_i$</th>
<th>$\mu_1 \neq 0$</th>
</tr>
</thead>
<tbody>
<tr>
<td>treatment T2 $\alpha_2 \neq 0 \Leftrightarrow \mu_1 \neq \mu_2$</td>
<td></td>
</tr>
<tr>
<td>treatment T3 $\alpha_3 \neq 0 \Leftrightarrow \mu_1 \neq \mu_3$</td>
<td></td>
</tr>
<tr>
<td>treatment T4 $\alpha_4 \neq 0 \Leftrightarrow \mu_1 \neq \mu_4$</td>
<td></td>
</tr>
<tr>
<td>treatment T5 $\alpha_5 \neq 0 \Leftrightarrow \mu_1 \neq \mu_5$</td>
<td></td>
</tr>
</tbody>
</table>

The results output by R show that there is a significant difference between the placebo and treatments 2, 3 and 4. In this setting, the placebo was the natural reference. However, it is possible to take another reference, or a linear constraint, using the instruction C(), as shown in the next example:

```r
> summary(lm(times~C(treatment,base=2)))
Call:
  lm(formula = times ~ C(treatment, base = 2))
Residuals:
   Min 1Q Median 3Q Max
-3.16667 -0.87500 -0.08333 0.83333 2.83333
Coefficients:
     Estimate Std. Error  t value
(Intercept) 5.0000 0.6245 8.006
C(treatment, base = 2)1 2.5000 0.8832 2.831
C(treatment, base = 2)3 -0.6667 0.8832 -0.755
C(treatment, base = 2)4 0.1667 0.8832 0.189
C(treatment, base = 2)5 1.1667 0.8832 1.321

Pr(>|t|)  
(Intercept) 0.0000000232 ***
C(treatment, base = 2)1 0.00903 **
C(treatment, base = 2)3 0.45739
C(treatment, base = 2)4 0.85184
C(treatment, base = 2)5 0.19847
---
Signif. codes:  0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
Residual standard error: 1.53 on 25 degrees of freedom
Multiple R-squared: 0.384,  Adjusted R-squared: 0.2854
F-statistic: 3.896 on 4 and 25 DF,  p-value: 0.01359
```

Fisher’s test does not change, since it does not depend on the linear constraint, but the estimates and the individual Student tests do change. With these results, we cannot show that treatment 2 is different to treatments 3, 4 and 5, but we do get a significant Student test for the comparison of the placebo with treatment 2.
Note that you can use the function `model.matrix()` on the fitted linear model to get the matrix of explanatory variables. In the ANOVA model with a constraint of the type $\alpha_i = 0$, the matrix includes an intercept (a column of 1s) and the $I-1$ indicator variables.

### 13.1.4 Validation of assumptions

**Validation of assumptions**: The ANOVA model corresponds to a linear model with a qualitative explanatory variable. The assumptions of the model can be validated using the method of analysis of residuals we presented for the regression model. Recall that the plot of residuals is obtained with the instructions:

```r
> par(mfrow=c(2,2))
> plot(model,col.smooth="red")
```

![Residuals vs Fitted](image1)
![Normal Q-Q](image2)
![Scale-Location](image3)
![Constant Leverage](image4)

Fig. 13.2: Analysing the residuals in single-factor ANOVA

In ANOVA, it is also possible to use a test of equality of variances to explore whether the assumption of homoscedasticity is admissible. Bartlett’s test (under normality in the subpopulations) can be obtained by...
13 Elementary analysis of variance

> bartlett.test(times˜treatment)
Bartlett test of homogeneity of variances
data: times by treatment
Bartlett’s K-squared = 2.4197, df = 4, p-value = 0.6591

However, this test is not robust to non-normality. In that case, use Levene’s test [25]:

> levene.test(times,treatment) # Available in package car.
Levene's Test for Homogeneity of Variance (center = median)
     Df F value Pr(>F)
group  4 0.5851 0.6763
25

13.1.5 Multiple comparisons and contrasts

Multiple comparisons: If, after performing analysis of variance, we reject the hypothesis of equal means relative to a factor with I levels, an interesting question is which means are significantly different from the others. In the fever button example, we would like to select the most efficient treatment, i.e. the one which leads to the fastest scarring.

The individual Student test in the linear model is perfectly valid to compare two treatments chosen in advance. However, it cannot be used to compare (for example) the treatment which seems to give the best results with the treatment which seems to give the worse results. Indeed, this would be equivalent to comparing all pairs of treatments. Each test has probability \( \alpha \) (the level of the test) of showing as present a difference which does not exist. Overall, out of the \( I(I-1)/2 \) possible comparisons, the probability that one is declared significant “at random” becomes important. There are several methods to control the global risk for the \( I(I-1)/2 \) pairwise comparisons.

The function `pairwise.t.test()` performs all pairwise comparisons and includes several methods to correct the risk \( \alpha \) in order to take into account the problem of multiple tests.

> pairwise.t.test(times,treatment,p.adjust="bonf")
Pairwise comparisons using t tests with pooled SD
data: times and treatment
Placebo T2 T3 T4
T2 0.090 - - -
T3 0.014 1.000 - -
T4 0.140 1.000 1.000 -
T5 1.000 1.000 0.483 1.000
P value adjustment method: bonferroni
R gives p-values adjusted with Bonferroni’s correction: the corrected p-values are given by multiplying the p-values from the Student tests by the number of tests. Given the results (p-value = 0.014 between treatment 1 and treatment 3), there is a significant difference between treatment 1 (placebo) and treatment 3, at the 5% level.

The comparison between treatment 1 and treatment 3 was performed by analysing model 1. The p-value for the individual Student test was 0.0014. Since ten comparisons were performed, this p-value is multiplied by 10 in Bonferroni’s method.

Many other correction methods exist. For single factor analysis of variance with the same number of observations in each group, Tukey’s method [30] is the most accurate. It gives simultaneous confidence intervals for the difference $\mu_i - \mu_j$ where $1 \leq i < j \leq I$.

```r
> my.aov <- aov(times ~ treatment)
> TukeyHSD(my.aov)

Tukey multiple comparisons of means
95% family-wise confidence level
Fit: aov(formula = times ~ treatment)
$ treatment
       diff lwr  upr  p adj
T2-Placebo -2.5000000 -5.0937744  0.09377442  0.0627671
T3-Placebo -3.1666667 -5.7604411 -0.57289224  0.0113209
T4-Placebo -2.3333333 -4.9271078  0.26044109  0.0927171
T5-Placebo -1.3333333 -3.9271078  1.26044109  0.5660002
T3-T2  -0.6666667 -3.2604411  1.92710776  0.9410027
T4-T2   0.1666667 -2.4271078  2.76044109  0.9996956
T5-T2   1.1666667 -1.4271078  3.76044109  0.6812222
T4-T3   0.8333333 -1.7604411  3.42710776  0.8770466
T5-T3   1.8333333 -0.7604411  4.42710776  0.2614661
T5-T4  1.0000000 -1.5937744  3.59377442  0.7881333
```
The results from Tukey’s method agree with those from Bonferroni’s method: the only confidence interval which does not contain the value 0 is the one for the difference between treatment 3 and treatment 1. There is a significant difference between treatment 1 and treatment 3. Since scarring time is shorter with treatment 3, we suggest using treatment 3.

### Contrast analysis

In ANOVA, a contrast (noted $L$) is defined as a linear combination of theoretical means with sum of coefficients equal to zero:

$$L = \sum_{i=1}^{I} \lambda_i \mu_i = \lambda^T \mu \quad \text{with} \quad \sum_{i=1}^{I} \lambda_i = 0$$

where $\mu = (\mu_1, \ldots, \mu_I)^T$ and $\lambda = (\lambda_1, \ldots, \lambda_I)^T$.

Contrasts are used to compare the means of groups of levels. For example, in the fever button example, to compare treatments 2 and 3, you should use the contrast $L_1 = \lambda^T \mu$ with $\lambda = (0, 1, -1, 0, 0)^T$ and perform the test $H_0 : L_1 = 0$ against $H_1 : L_1 \neq 0$.

You can perform tests on contrasts with the function `fit.contrast()` from package gregmisc.
Note

The same result was given by the individual Student test in model 2.

Now suppose that treatments 2 and 3 are ointments but treatments 4 and 5 are anti-tobacco patches. To compare the two types of remedies, you can use the contrast \( L_2 = \lambda^T \mu \) with \( \lambda = (0, -1, -1, 1, 1)^T \) and perform the test \( H_0 : L_2 = 0 \) against \( H_1 : L_2 \neq 0 \).

\[
\begin{align*}
\text{treatment: 2 against 3} & : 0.6666667 \quad 0.883176 \quad 0.7548514 \\
\text{Pr(>|t|)} & \\
\text{treatment: 2 and 3 against 4 and 5} & : 2.0000000 \quad 1.249000 \\
\text{t value Pr(>|t|)} & \\
\text{treatment: 2 against 3} & : 0.7548514 \quad 0.4573908 \\
\text{treatment: 2 and 3 against 4 and 5} & : 1.6012815 \quad 0.1218767
\end{align*}
\]

13.1.6 Summary

The next table presents the main functions for single factor analysis of variance.

13.2.1 Aims, data and model

- **Aim:** ANOVA with two factors, or two-way ANOVA, is a method to explain a quantitative variable with two “crossed” explanatory qualitative variables (called factors).

- **Data:** Let A be a factor with I modalities and B a factor with J modalities. For each couple \((i, j)\), \(i = 1, \ldots, I\) and \(j = 1, \ldots, J\), we observe a quantitative variable \(Y\), \(n_{ij}\) times. We assume that \(Y\) follows a normal distribution \(N(\mu_{ij}, \sigma^2)\) in each subpopulation defined by values \(i\) and \(j\) of the two factors.

- **Model:** The model is written

\[
Y_{ijk} = \mu_{ij} + \epsilon_{ijk}, \quad \text{for} \quad k = 1, \ldots, n_{ij}, \quad i = 1, \ldots, I, \quad j = 1, \ldots, J,
\]

where the errors \(\epsilon_{ijk}\) are independent random variables from a \(N(0, \sigma^2)\) distribution.

In this model, the real parameters \(\mu_{11}, \ldots, \mu_{1I}, \ldots, \mu_{1J}, \ldots, \mu_{IJ}\) are unknown, as is the variance \(\sigma^2\).

We decompose \(\mu_{ij}\) so that the effects of the factors A and B appear, as well as the effect of their interaction:

\[
\mu_{ij} = \mu_{**} + \alpha_i^A + \alpha_j^B + \beta_{ij}
\]

with

- \(\mu_{**} = \frac{1}{IJ} \sum_{i=1}^{I} \sum_{j=1}^{J} \mu_{ij}\): general mean effect;
- \(\mu_{i*} = \frac{1}{J} \sum_{j=1}^{J} \mu_{ij}\): effect of level \(i\) of factor A;
- \(\alpha_i^A = \mu_{i*} - \mu_{**}\): differential effect of level \(i\) of factor A;
- \(\mu_{*j} = \frac{1}{I} \sum_{i=1}^{I} \mu_{ij}\): effect of level \(j\) of factor B;
- \(\alpha_j^B = \mu_{*j} - \mu_{**}\): differential effect of level \(j\) of factor B;
- \(\beta_{ij} = \mu_{ij} - \mu_{**} - \alpha_i^A - \alpha_j^B\): interaction effect of level \(i\) of factor A and level \(j\) of factor B.
By construction, \( \sum_{i=1}^{I} a_i^A = 0 \), \( \sum_{j=1}^{J} a_j^B = 0 \) and \( \forall i, \sum_{j=1}^{J} \beta_{ij} = 0 \).

The aim here is to detect

- whether factor A has an effect on the quantitative variable Y;
- whether factor B has an effect on the quantitative variable Y;
- and whether there is an interaction effect between factors A and B on the quantitative variable Y.

### 13.2.2 Example and graphical inspection

#### Example of use:

The next table gives the yield of einkorn wheat from fields in four different regions with three types of fertilizer.

<table>
<thead>
<tr>
<th>Region I</th>
<th>Region II</th>
<th>Region III</th>
<th>Region IV</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fertilizer ( E_1 )</td>
<td>15 14 17</td>
<td>21 20 21</td>
<td>14 15 14</td>
</tr>
<tr>
<td>Fertilizer ( E_2 )</td>
<td>16 19 20</td>
<td>23 24 25</td>
<td>15 14 14</td>
</tr>
<tr>
<td>Fertilizer ( E_3 )</td>
<td>18 17 17</td>
<td>20 21 21</td>
<td>17 19 17</td>
</tr>
</tbody>
</table>

These data are input in R with the following instructions:

```r
> yield <- c(15,14,17,21,20,21,14,15,14,16,17,17,16,19,20,23,24,25,15,14,14,12,11,12,18,17,17,20,21,21,17,19,12,13,13)
> fertilizer <- gl(3,12,36,labels=paste("Fertilizer",1:3))
> region <- gl(4,3,36,labels=paste("Region",1:4))
> wheat <- data.frame(yield,fertilizer,region)
```

We wish to study the effect of the type of fertilizer (\( E_1 \), \( E_2 \) ou \( E_3 \)) on the yield per hectare of einkorn wheat and to find out whether there is a significantly different yield between the four regions.

#### Graphical inspection:

In this example, the data are balanced (there is the same number of observations for each pair of factor levels). When this is not the case, the ANOVA table is no longer unique; we advise you to use a decomposition of variance of type III (see [31]).
the modalities of the other factor. This flexibility in the model can be visual-
ized. The command to explore this interaction is `interaction.plot()`. The
function `plotMeans()`, available in the package `Rcmdr`, also allows graphi-
cal inspection of the interaction.

```r
> interaction.plot(region, fertilizer, yield)
```

![Graph showing interaction plot](image)
13.2 Analysis of variance with two factors

> interaction.plot(fertilizer, region, yield)

Fig. 13.3: Exploration of interaction in two-way ANOVA.

These plots indicate that there seems to be interaction (the lines intersect).

### 13.2.3 ANOVA table, tests, and parameter estimation

- **R instruction for ANOVA table:** Several functions exist to perform two-way ANOVA with interaction: `aov()`, `anova(lm())` and `Anova()` (in package `car`).

> model2 <- summary(aov(yield ~ region + fertilizer, data=wheat))
> model2

Warning

When you have only one observation per combination of modalities of the factors A and B (i.e. \( n_{ij} = 1 \) \( \forall i, j \)), you can only estimate two-way ANOVA without interaction.

\[
aov(yield \sim region + fertilizer).
\]
Df  Sum Sq  Mean Sq    F value   Pr(>F)
region      3   327.19  109.065   112.1810  2.955e-14  ***

> anova(lm(yield~region*fertilizer,data=wheat))
Analysis of Variance Table
Response: yield

Df  Sum Sq  Mean Sq    F value   Pr(>F)
region      3   327.19  109.065   112.1810  2.955e-14  ***
fertilizer  2     0.89  0.4441   0.4571   0.6385
region:fertilizer  6   99.56  16.593   17.0667  1.359e-07  ***
Residuals   24    23.33  0.972

Signif. codes:  0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1

> Anova(lm(yield~region*fertilizer,data=wheat))
Anova Table (Type II tests)
Response: yield

Df Sum Sq  Mean Sq    F value   Pr(>F)
region      3   327.19  112.1810  2.955e-14  ***
fertilizer  2     0.89  0.4571   0.6385
region:fertilizer  6   99.56  17.0667  1.359e-07  ***
Residuals   24    23.33

Signif. codes:  0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1

Note
The formula `region*fertilizer`, used in `aov()` and `lm()`, corresponds in fact to the formula `region+fertilizer+region:fertilizer`, i.e. the factor region, the factor fertilizer, and the interaction of these two factors.

The p-value associated with the test of interaction is significant. This implies that the effect of fertilizer of yield can be different depending on the region.

Warning
We consider that there is no interaction effect if the associated p-value is greater than 5%. In this case, we perform an ANOVA without an interaction term which makes it easier to interpret the principal effect. When there is interaction, do not interpret the principal effects in the ANOVA table output.

Test of conditional effects with interaction: For example, we wish to know whether there is a fertilizer effect in region 1. To this end, we use the function `subset()`, which only uses data from a given region.
13.2 Analysis of variance with two factors

```r
> fertilizer.region1 <- summary(aov(yield ~ fertilizer, subset=region="Region 1"))
> fertilizer.region1

<table>
<thead>
<tr>
<th>Df</th>
<th>Sum Sq</th>
<th>Mean Sq</th>
<th>F value</th>
<th>Pr(&gt;F)</th>
</tr>
</thead>
<tbody>
<tr>
<td>fertilizer</td>
<td>2</td>
<td>14.0000</td>
<td>7.0000</td>
<td>3.0000</td>
</tr>
<tr>
<td>Residuals</td>
<td>6</td>
<td>14.0000</td>
<td>2.3333</td>
<td></td>
</tr>
</tbody>
</table>
```

Warning: The test in this ANOVA table corresponds to ANOVA with one factor (fertilizer) of the yield of wheat in region 1. It does not take into account any information from data in the other regions, which would allow for a better estimation of the residual variance. To test the fertilizer effect in region 1, divide the mean square of the fertilizer factor found in the ANOVA restricted to region 1 by the mean residual square of the ANOVA with interaction:

```r
> F.fertilizer.region1 <- fertilizer.region1[[1]]$Mean[[1]] / model2[[1]]$Mean[[4]]
> pvalue <- 1 - pf(F.fertilizer.region1, df1=2, df2=24)
> pvalue
[1] 0.003552714
```

The p-value is less than 5%, hence we conclude that there is a fertilizer effect in region 1.

Parameter estimation: The parameters can be estimated with the function summary() for the model `lm(yield ~ region * fertilizer)`. Recall that R imposes the constraints $\alpha_1^A = 0$, $\alpha_1^B = 0$, $\beta_{ij} = 0 \forall j = 1, \ldots, J$ and $\beta_{i1} = 0 \forall i = 1, \ldots, I$.

```r
> summary(lm(yield ~ region * fertilizer))

Call:
  lm(formula = yield ~ region * fertilizer)

Residuals:
     Min      1Q  Median      3Q     Max
-2.3333 -0.6667  0.1667  0.3333  1.6667

Coefficients:
            Estimate Std. Error t value
(Intercept) 15.3333   0.5693 26.9156
regionRegion 2  5.3333   0.8051   6.6042
regionRegion 3 -1.0000   0.8051  -1.2438
regionRegion 4  1.3333   0.8051   1.6525
fertilizerFertilizer 2  3.0000   0.8051   3.7196
fertilizerFertilizer 3  2.0000   0.8051   2.4723
regionRegion 2:fertilizerFertilizer 2  0.3333   1.1386
regionRegion 3:fertilizerFertilizer 2 -3.0000   1.1386
regionRegion 4:fertilizerFertilizer 2 -8.0000   1.1386
regionRegion 2:fertilizerFertilizer 3 -2.0000   1.1386
regionRegion 3:fertilizerFertilizer 3  1.3333   1.1386
```
Thus the intercept corresponds to the estimate of the mean yield for fertilizer 1 in region 1. For example, the coefficient associated with region 2 corresponds to the estimate of the difference of the mean yield with fertilizer 1 if region 2 and the mean yield with fertilizer 1 if region 1. The Student tests associated with the factors can therefore be interpreted. However, those associated with the estimates of the crossed factors coefficients are not relevant.

Note

In this example, there is no particular reason of choosing this constraint. To change it, use the function C(). For example:

```r
summary(lm(yield ~ C(region,sum)*C(fertilizer,sum)))
```

corresponds to the constraints $\sum_{i=1}^{I} \alpha_i^A = 0$, $\sum_{j=1}^{J} \alpha_j^B = 0$ and $\forall i$, $\sum_{j=1}^{J} \beta_{ij} = 0$, $\forall j$, $\sum_{i=1}^{I} \beta_{ij} = 0$.

### 13.2.4 Validating assumptions

- **Validating assumptions:** As in one-way ANOVA, we validate the model with a study of the residuals of the underlying linear model.
However, if the data size is large enough for each pair of factor modalities, it is better to check for normality in each subpopulation and for homoscedasticity.
13.2.5 Contrasts

**Contrast method:** We refer the reader to the definition of contrasts given for one-way ANOVA.

For example, suppose we wish to know whether there is a significant difference of yield in region 1 between fertilizers 1 and 2. We perform a contrast test using the function `estimable()` from package `gmodels`.

```r
> mod.inter <- lm(yield ~ fertilizer:region-1)
> cm <- rbind("F1 vs F2 in R1"=
+ c(1,-1,0,0,0,0,0,0,0,0,0,0))
> estimable(mod.inter,cm)
```

| Estimate | Std. Error | t value | DF | Pr(>|t|) |
|----------|------------|---------|----|----------|
| F1 vs F2 in R1 | -3 | 0.8050765 | -3.726354 | 24 | 0.001048837 |

We get the same p-value as with the test for estimating model parameters.

Another example of use of the method of contrasts is the comparison of the yield with fertilizer 1 in the Southern regions (regions 1 and 2) with the Northern regions (regions 3 and 4):

```r
> cm <- rbind("F1 vs F2 in R1"=
+ c(1,-1,0,0,0,0,0,0,0,0,0,0),

</tbody>
</table>
Warning

For two-way ANOVA with unbalanced data, you should use a decomposition of the sums of squares of type III (see [31]).

```r
> model.lm <- lm(yield ~ region * fertilizer, contrasts=list(region=contr.sum, fertilizer=contr.sum))
> Anova(model.lm, type="III")
```

Remember to use the option contrasts in function `lm()`.

### SECT 13.3

Revised measures analysis of variance

This section is a brief introduction to repeated measures ANOVA models. We first introduce some vocabulary to better understand the three models introduced in this section.

A fixed effects model is a model where all explanatory variables (factors) are treated as non-random (controlled, for example). A random effects model or mixed effects model occurs when some or all explanatory variables are assumed to be random.

In ANOVA, a statistical unit is called a “subject”. When a dependent variable is measured on groups of independent subjects, where each group is exposed to a different condition, the set of conditions is called a between-subjects factor. The models in sections 13.1 and 13.2 only use such factors.

In the case where each subject has a measure of the dependent variable for all modalities of the factor, this factor is called a within-subjects factor. An experiment has within-subjects design when at least one factor is within-subjects. Such experimental designs are also called repeated-measures designs, since within-subjects factors always imply repeated measures on each subject. By construction, this is equivalent to considering an extra random factor, the subject factor.

When an analysis includes both within-subjects and between-subjects factors, it is called a repeated measures ANOVA with between-subjects factors, mixed-design
13.3.1 One-way repeated measures ANOVA

- **Aim:** We consider the case where for each subject \( s \) (out of \( n \)), we measure the response (dependent) variable \( Y \) for each of the \( I \) modalities of the fixed-effects factor \( X \).

- **Example:** For 15 minutes, we count how many times each of seven rats presses a lever, in three reinforcement conditions. In the first condition, the rat is given well-liked food, in the second average-liked food, and in the third less-liked food. The results are given in the following table:

<table>
<thead>
<tr>
<th>Subject</th>
<th>cond_1</th>
<th>cond_2</th>
<th>cond_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>s_1</td>
<td>8</td>
<td>6</td>
<td>2</td>
</tr>
<tr>
<td>s_2</td>
<td>6</td>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td>s_3</td>
<td>7</td>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>s_4</td>
<td>9</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>s_5</td>
<td>5</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>s_6</td>
<td>7</td>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>s_7</td>
<td>6</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

- **Model:** The underlying model is a mixed-effects model:

\[
Y_{si} = \mu_i + \pi_s + \epsilon_{si}, \quad s = 1, \ldots, n, \ i = 1, \ldots, I
\]

where \( \mu_i \) measures the fixed effect of modality \( i \) of factor \( X \), the \( \pi_s \) are independent random variables following a \( N(0, \sigma_{\pi}^2) \) distribution, to take into account the dependence between measures made on individual \( s \), the \( \epsilon_{si} \) are independent random variables following a \( N(0, \sigma^2) \) distribution. We also assume that the \( \pi_s \) and the \( \epsilon_{si} \) are independent. By construction, this single factor model with repeated measures is in fact a two-factor model: one fixed within-subjects factor (X) and one random factor, the subject factor.

- **R instructions:**

```r
summary(aov(Y ~ X + Error=subject/X, data=my.data.frame))
```

where `my.data.frame` is a data.frame containing variables \( Y \) and \( X \), and a variable `subject` giving the subject ID number. The variables \( X \) and `subject` must **necessarily** be defined as factors.
13.3 Repeated measures analysis of variance

Note
You can also use the function \texttt{lme()} included in package \texttt{nlme}:
\begin{verbatim}
anova(lme(Y ∼ X,random= 1|subject,data=my.data.frame))
\end{verbatim}

\begin{itemize}
  \item \textbf{Back to the example:}
  \begin{verbatim}
rat <- data.frame(lever=c(8,6,2,6,5,1,7,5,0,9,3,5,4,1,
+ 7,5,2,6,2,0),subject=gl(7,3,21),cond=gl(3,1,21))
> summary(aov(lever˜cond+Error(subject/cond), data=rat))
Error: subject
  Df Sum Sq Mean Sq F value Pr(>F)
Residuals 6 15.905 2.6508
Error: subject:cond
  Df Sum Sq Mean Sq F value Pr(>F)
cond  2 108.86  54.429 47.297 0.000002036 ***
Residuals 12 13.81  1.151
---
Signif. codes: 0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
\end{verbatim}
\end{itemize}

13.3.2 Two factor model with repeated measures for both factors

\begin{itemize}
  \item \textbf{Aim:} We consider the case where for each subject \(s\) (out of \(n\)), the response variable \(Y\) is measured for each of the \(I \times J\) combinations of modalities of two fixed effects factors A and B.
  \item \textbf{Example:} A scientist wishes to study the effect of lecithin on memory issues. Four subjects receive a daily treatment. After one, two and six months of treatment, each subject undergoes two tests (Test 1 and Test 2). The results are shown in the following table:

\begin{tabular}{|c|ccc|ccc|}
  \hline
  & Test 1 & & & Test 2 & & \\
  subject & M1 & M2 & M3 & M1 & M2 & M3 \\
  \hline
  \(s_1\) & 10 & 11 & 9 & 3 & 6 & 3 \\
  \(s_2\) & 18 & 20 & 17 & 16 & 20 & 14 \\
  \(s_3\) & 6 & 8 & 8 & 5 & 6 & 3 \\
  \(s_4\) & 4 & 9 & 9 & 10 & 10 & 6 \\
  \hline
\end{tabular}

\item \textbf{Model:} The underlying model is a mixed model:
\begin{equation}
Y_{sij} = \mu_{**} + \alpha_{i}^A + \alpha_{j}^B + \beta_{ij} + \pi_{s} + \pi_{si}^A + \pi_{sj}^B + \epsilon_{sij}
\end{equation}
with \(s = 1, \ldots, n\), \(i = 1, \ldots, I\), \(j = 1, \ldots, J\) and where the terms \(\mu_{**}, \alpha_{i}^A\), \(\alpha_{j}^B\) and \(\beta_{ij}\) were defined in Section 13.2. The random effect subject is represented by the i.i.d. random variables \(\pi_{s}\) with distribution \(N(0, \sigma_{\pi}^2)\). The i.i.d.
random variables $\pi_{si} \sim \mathcal{N}(0, \sigma_{\pi}^2)$ measure the random interaction effects between the subject factor and the fixed factor A. The i.i.d. random variables $\pi_{ij}^B \sim \mathcal{N}(0, \sigma_{\pi}^2)$ measure the random interaction effects between the subject factor and the fixed factor B. The errors $\epsilon_{si}$ are i.i.d. variables following the distribution $\mathcal{N}(0, \sigma^2)$. Furthermore, we assume that the errors are independent of the $\pi_s$, $\pi_{si}^A$ and $\pi_{ij}^B$.

**R instructions:**

```r
summary(aov(Y ~ A*B + Error(subject/(A*B)),data=my.data.frame))
```

**Back to the example**

```r
> lecithin <- data.frame(memory=c(10,11,9,3,6,3,18,20,17,16,20,14, + 6,8,5,6,3,4,9,10,10,10,24), subject=gl(4,6,24), + test=gl(2,3,24),month=gl(3,1,24))
> summary(aov(memory~month*test+Error(subject/(test*month)), + data=lecithin))
Error: subject
 Df Sum Sq Mean Sq F value Pr(>F)
Residuals 3 508.13 169.38
Error: subject:test
 test 1 30.375 30.375 2.2158 0.2333
 Residuals 3 41.125 13.708
Error: subject:month
 month 2 32.25 16.1250 16.826 0.003465 **
 Residuals 6 5.75 0.9583
---
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
Error: subject:test:month
 month:test 2 12.25 6.125 2.3333 0.1780
 Residuals 6 15.75 2.625
```

### 13.3.3 Two factors model with repeated measures for one factor

**Aim:** We are interested in the case where subjects are allocated to groups defined by the $I$ modalities of fixed factor A. For each subject, we measure the response variable for all $J$ modalities of fixed factor B.

**Example:** In an experiment, the subjects estimate the length of a metal bar. The bars are of three different lengths. Two groups of four distinct subjects are created. In each group, each subject is shown three bars of different lengths.

\[ Y_{s(i)} = \mu \cdot \cdot + \alpha_{A}^{s} + \alpha_{B}^{j} + \beta_{ij} + \pi_{A}^{s} + \epsilon_{s(i)} , \quad s = 1, \ldots, n, \ i = 1, \ldots, I, \ j = 1, \ldots, J \]

where the \( \pi_{A}^{s} \) are i.i.d. random variables with distribution \( N(0, \sigma_{\pi}^{2}) \) measuring the random effects of the modalities \( s \) of the subject factor. The errors \( \epsilon_{s(i)} \) are i.i.d. random variables with distribution \( N(0, \sigma^{2}) \). Furthermore, we assume that the \( \epsilon_{s(i)} \) are independent of the \( \pi_{s(i)} \). The terms \( \mu \cdot \cdot \), \( \alpha_{A}^{s} \), \( \alpha_{B}^{j} \), \( \beta_{ij} \) were defined in Section 13.2. For the model to be identifiable, we have to impose the constraints \( \sum_{i=1}^{I} \alpha_{A}^{s} = 0 \), \( \sum_{j=1}^{J} \alpha_{B}^{j} = 0 \), \( \forall j \), \( \sum_{i=1}^{I} \beta_{ij} = 0 \), \( \forall i \), \( \sum_{j=1}^{J} \beta_{ij} = 0 \).

The realization \( y_{s(i)} \) of the random variable \( Y_{s(i)} \) represents the observation of the \( s \)th subject from \( i \)th group of factor A, for level \( j \) of factor B. The notation \( s(i) \) underlines the fact that the subject factor is nested in factor A.

**R instructions:**
```R
summary(aov(Y ~ A*B + Error(subject %in% A), data=my.data.frame))
```
or equivalently:
```R
summary(aov(Y ~ A*B + Error(subject:A), data=my.data.frame))
```

**Back to the example:**
```R
> bar.estim <- data.frame(bar=c(10,11,9,3,6,3,18,20,17,16,20,14,6,8,5,6,3,4,9,9,10,10,6),
+   subject=gl(4,6,24),
+   group=gl(2,3,24), # Factor A.
+   long=gl(3,1,24) # Factor B.
+ )
> summary(aov(bar ~ group*long +
+   Error(subject %in% group), data=bar.estim))

Error: subject:group

Df  Sum Sq Mean Sq  F value Pr(>F)
group 1   30.37  30.375   0.3318 0.5855
Residuals 6  549.25  91.542

Error: Within

Df  Sum Sq Mean Sq  F value Pr(>F)
long 2   32.25  16.125  3.4186 0.066833 .
Residuals 12  21.50  1.7917

---
Signif. codes: 0 ‘***’ 0.001 ‘**’ 0.01 ‘*’ 0.05 ‘.’ 0.1 ‘ ’ 1
Exercises

13.1- Give the instruction to perform ANOVA with one factor (noted A).
13.2- Give the instruction to perform ANOVA with two factors (noted A and B) with interaction.
13.3- Which test would you use to check for homoscedasticity in an ANOVA model?
13.4- Which instruction performs pairwise tests after single-factor ANOVA?
13.5- Which function gives the estimates for a single-factor ANOVA model?
13.6- Which function is used to choose the constraint in ANOVA?

Worksheet

A- Study of one-way ANOVA

• Study of noise levels

In order to study the influence of the factor “level of surrounding noise” on the ability of a subject to solve a problem, the following experiment is designed: twenty-four school children are randomly allocated to four rooms. Street noises were previously recorded and are played in each room at a specific noise level. The children must solve a series of problems. The response variable is the final grade for the series of problems. The results are given in the following table:
We wish to know whether there is an effect of the factor “level of surrounding noise” on a subject’s ability to solve a problem.

13.1- Input the data set in an adequate structure to perform ANOVA.
13.2- Write down the ANOVA model to answer the question.
13.3- Perform the analysis corresponding to your model.
13.4- Perform all pairwise comparisons of noise levels; remember to take into account the problem of multiplicity of tests.

• Study of intima-media

In the “Intima-media” study, we are interested in the relationship between intima-media thickness and alcohol consumption.

13.1- Download the intima-media data file.
13.2- Suggest a plot to visualize the differences in intima-media thickness depending on alcohol consumption.
13.3- Is there a difference of mean intima-media thickness depending on alcohol consumption?
13.4- Analyse the residuals to validate the assumptions of your statistical study.

• Study of physical activity

In a study of risky behaviour amongst people aged 14 to 25, a scientist observed offences (theft, racketeering, brawls...) committed by youngsters and weekly physical activity. Risky behaviour was measured on a scale from 0 to 100. A subset of the data is available at the URL http://www.biostatisticien.eu/springeR/sports.RData:

```
> print(sports[sample(1:105,10),],row.names=FALSE)
score  time
9 [2,3]
75 [0;1]
0 [3;4]
21 [2,3]
67 [4;5]
69 [1;2]
36 [2,3]
0 [3;4]
87 [0;1]
16 [2;3]
```
13.1- Describe the factors involved and write down the model (and the underlying assumptions).
13.2- Perform a test at the 5 % level to decide whether there is a significant effect between physical activity and risky behaviour.
We call “not athletic” youngsters who play sports for less than 2 hours per week, “somewhat athletic” those with weekly physical activity in the interval [2,4] and “very athletic” those who play sports at least 4 hours per week.
The scientist makes the following research assumptions:
• research assumption 1: “not athletic” youngsters have more risky behaviour than “somewhat athletic” youngsters;
• research assumption 2: risky behaviour is different between “very athletic” and “not athletic” youngsters.
13.3- Translate the research assumptions into contrasts.
13.4- Test these two assumptions at the 5 % level.

B- Study of two-way ANOVA

• Study of batteries

In an experiment on battery lifetime, the aim is to find battery life as a function of type of battery. It is known that battery lifetime depends on temperature, so a plane with two factors (temperature and type of battery) is created. The following table gives battery lifetime depending on these two factors.

<table>
<thead>
<tr>
<th>Type</th>
<th>15 °C</th>
<th>70 °C</th>
<th>125 °C</th>
</tr>
</thead>
<tbody>
<tr>

<td>150</td>
<td>139</td>
<td>60</td>
</tr>
</tbody>
</table>

13.1- Which factors are involved in this experiment? What are their modalities? What is the response variable?
13.2- Propose and define an ANOVA model for this data set.
13.3- Propose a graphical representation to visualize any interaction there may be in the model.
13.4- Estimate the parameters of the model.
13.5- Draw an ANOVA table for your model.
13.6- Perform the relevant tests to finalize this analysis.

• Milk yield
We are interested in the influence of type and quantity of food on milk yield. We have observed these Forty values:

13.1- Propose and define an ANOVA model to study the influence of type and quantity of food on milk yield.

13.2- Propose a graphical representation to visualize any interaction there may be in the model.

13.3- Estimate the parameters of the model.

13.4- Draw an ANOVA table for your model.

13.5- Perform the relevant tests to finalize this analysis.

• Intima-media study

In practical A, we looked at a possible relationship between intima-media thickness and alcohol consumption in the “Intima-media” study. We now wonder whether intima-media thickness is linked to alcohol consumption and tobacco consumption.

13.1- Download the intima-media data set.

13.2- Propose and define an ANOVA model to study the influence of tobacco consumption and alcohol consumption on intima-media thickness.

13.3- Propose a graphical representation to visualize any interaction there may be in the model.

13.4- Is there a difference in intima-media thickness depending on alcohol consumption? Depending on tobacco consumption?
Appendix: Installing R and R packages

Prerequisites and goals of this chapter

- No prerequisite. You may be interested in reading chapter 1 first.
- This chapter explains how to install R version x (replace throughout x by the number of the latest version) under Microsoft Windows XP, and how to install additional packages under Windows or Linux.

SECTION C.1

Installing R under Microsoft Windows XP

First download R (file R-x-win.exe where x is the number of the latest version) using your usual web browser from the URL http://cran.r-project.org/bin/windows/base/

Save this executable file on the Windows Desktop and double-click the file R-x-win.exe (its icon is).

The software then installs. All you have to do is follow the instructions displayed on your screen and keep the default options.

When the icon is added to the Desktop, installation is complete.
Many additional modules (called packages or libraries) are available on the website http://cran.r-project.org/web/packages/ available_packages_by_name.html or here: http://cran.r-project.org/ bin/ windows/contrib/, in the folder corresponding to the number x of your R version.

Packages extend the functionalities of R. We present several ways of installing a new package.

**C.2.1 Installing from a file on your disk**

For example, you can download from the website mentioned above the file: R2HTML_number.zip and save it on the Windows Desktop.

To install this package, first start R by double-clicking its icon. Go to the menu Packages, in the sub-menu Install package(s) from zip files...

Select the file R2HTML_number.zip on the Windows Desktop then click on “Open”.
C.2 Installing additional packages

C.2.2 Installing directly from Internet

For example, to install packages car and Rcmdr, first launch R by double-clicking its icon on the Desktop.

Then go to menu Packages, and sub-menu Install package(s)...

Choose a CRAN mirror close to your location and click OK.

At the next step, select the entries “car” and “Rcmdr”.

To do this, first click on “car” then scroll down and click on “Rcmdr” while pressing on the CTRL key. Check that both entries have been selected (highlighted in blue).
Click “OK”. You should see the two following screens, indicating that the packages you selected are being installed.

Warning

This procedure may fail, for example if your system administrator has blocked access to some websites with a firewall, has imposed a proxy to surf the Internet or has forbidden writing in some Windows folders. If you encounter a problem, we advise you to contact your administrator. Note that you can force R to use a proxy, and that you can install packages locally in your own home directory. You can consult sections 2.15 (How do I set environment variables?) or 2.19 (The Internet download functions fail) of the Windows FAQ available here: http://cran.r-project.org/bin/windows/base/rw-FAQ.html

C.2.3 Installing from the command line

You can use R without the menus of the graphical user interface. This is the case for example under Unix/Linux, where R does not have a graphical user interface. In that case, use the following commands to install packages:

- to install a package from a *.zip file on your hard disk:
  ```r
  install.packages(choose.files(), repos = NULL)
  ```
- to install a package (say Rcmdr) from the CRAN website:
Another possibility is to install a package without going through R, directly from an MS-DOS command window under Microsoft or from a terminal under Linux or MacOS. In that case, you will need many compilation tools. If these tools are not installed on your computer, refer to the section on package creation in chapter 7.

If these tools are installed on your computer, you can try this:

For example, download the file (package source) Rcmdr_number.tar.gz from the URL http://cran.r-project.org/src/contrib/Descriptions/Rcmdr.html. Save it (on the Desktop) and start an MS-DOS window (Start menu/Run/cmd), then enter:

```
cd Desktop
R CMD INSTALL Rcmdr_number.tar.gz (replace number with the relevant number).
```

C.2.4 Installing packages under Linux

Note that the commands of the previous section also work under Linux. But sometimes, you need to be logged in as root to use them (command su - in a terminal window).

If you do not have root access, you can still install packages locally, in your home directory. For example, for package Rcmdr, type in a terminal:

```
R CMD INSTALL --library=/home/user/Rlibs Rcmdr_number.tar.gz
```

(you should first have created the folder Rlibs with the command mkdir Rlibs, and should replace /home/user/Rlibs with the appropriate path and number with the appropriate number).

Finally, so that R knows where to look for installed packages, you must create a file ~/.Renviron containing the line

```
R_LIBS=/home/user/Rlibs
```

Tip

If your computer is behind a firewall and you need to use a proxy to go online, you can use the following command to install a package directly from R:

```
install.packages("Rcmdr")
```
SECTION C.3

Loading installed packages

Warning

To understand this section, you need to have a rough understanding of the difference between your computer’s random access memory (RAM) and physical memory.

*Installing* a package means that its files are “written” physically on the hard disk: when you turn your computer off then on again, the files are still in the same place. You will not need to reinstall the package, unless you need an updated version. On the contrary, *loading* a package (to the memory) means that it is temporarily at the user’s disposal in R. But if you close and reopen R, the package is no longer available; you need to load it again.

To sum up, once you have installed a package on your computer’s hard disk, you have to load it to R’s memory before you can use it. For example, if you type in the R console:

```
Commander()
```

you should see the following error message, which indicates that the package including this function cannot be accessed by R:

```
Error: cannot find function "Commander"
```

You must first load Rcmdr to the memory. To do this, you can either type `require(Rcmdr)` in the console, or go to the menu Packages/Load package...
and use the mouse to load package \texttt{Rcmdr}.

The following window then appears.
Close it, and type once again in the R console:

Commander()

Note that the package Rcmdr has been loaded and that this command no longer returns an error message.

Tip

Note that R offers the possibility of automatically loading some packages upon start-up:

.First <- function() {
  require(pkg1) # Replace pkg1 with the
  # name of the desired package
  require(pkg2)
  # and so on.
}

Indeed, the functions .First() and .Last() specify instructions to be executed when you start and exit R, respectively.

**Note:** The commands and symbols listed are from the R programming language, a software environment for statistical computing and graphics. The index provides a comprehensive list of functions and symbols, along with their page numbers for easy reference. This is useful for users looking to understand or utilize specific features within R. Each entry is categorized by command, with detailed descriptions and related functions, facilitating a deeper understanding of R's extensive capabilities.

Solutions to Exercises

Solutions to Exercises from Chapter 1

1.1-  [1]  1  2  3  4  5  6  7  8  9
1.2-  [1]  2  4  6  8  10
1.3- The instruction var<-3 does not output anything. The instruction Var*2 outputs an error message because Var has not yet been defined.
1.4- The instruction x<-2 does not output anything. The instruction 2x<-2*x outputs an error message because a variable name should not begin with a number.
1.5- The instruction root.of.four <- sqrt(4) does not output anything. The instruction root.of.four outputs [1] 2
1.6- The instruction x<-1 does not output anything. The instruction x<- -1 outputs [1] FALSE
1.7- The instruction An even number <- 16 outputs an error message because a variable name should not contain spaces.
1.8- The instruction "An even number" <- 16 does not output anything.
1.9- The instruction "2x" <- 14 does not output anything.
1.10- The instruction An even number outputs an error message.
1.11- >2 +
    + 4
    [1] 6
1.13- The 6 R data types are: numeric, complex, logical, character, raw.
1.14- X <- matrix(1:12,nrow=4,ncol=3,byrow=FALSE)
1.15- The R data structures are: c(), matrix(), array(), list(), data.frame(), factor(), ordered().
Solutions to Exercises from Chapter 2

2.1- The three main R functions to use to import data from an ASCII text file are: `read.table()`, `scan()` and `read.ftable()`.

2.2- header: a logical value indicating whether the file contains the names of the variables as its first line (e.g.: `header=TRUE`).
sep: the field separator character. Values on each line of the file are separated by this character (e.g.: `sep=" "` or `sep="\t"`).
dec: the character used in the file for decimal points (e.g.: `dec="."` or `dec=","`).
row.names: a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names (e.g.: `row.names=2`).
skip: the number of lines of the data file to skip before beginning to read data (e.g.: `skip=4` to exclude the first 4 lines from reading).
nrows: the maximum number of rows to read in (e.g.: `row.names=19`).

2.3- Function `readLines()` reads some or all text lines from a connection.

2.4- Function `fix()` enables one to modify a `data.frame` or a matrix using a small spreadsheet.

2.5- `read.csv()`: reads a comma separated value file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file (note: `dec="."`).
`read.csv2()`: reads a semicolon separated value file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file (note: `dec=","`).
`read.delim()`: reads a tabulated separated value file (note: `dec="."`).
`read.delim2()`: reads a tabulated separated value file (note: `dec=","`).

2.6- Function `read.ftable()` reads, writes and coerces flat contingency tables.

2.7- Function `scan()` should be used when data are not organised in table format. Function `read.table()` is used for table format data sets.

2.8- Importing data from an Excel sheet:
  - Using copy-paste: select the data under Excel, copy these data to the clipboard, use the instruction:
    ```r
    x <- read.table(file("clipboard"), sep="\t", header=TRUE, dec=",")
    ```
  - Using an intermediate ASCII file: save the Excel sheet as .txt (separator: TAB), then use function `read.table()`.
  - Using package `gdata` and function `read.xls()`.

2.9- Package `foreign`.

2.10- The `colClasses` argument from function `read.table()` can be used to indicate the type of each column, and thus greatly increases the speed of reading of huge data sets.
2.11- Function write.table() enables one to write in a file the data set contained in a data.frame. Another function is write() that should be used for vector or matrix objects.

2.12- Here are four basic functions to build vectors:
• c()
• seq()
• rep()
• " : " (example 1:10)

2.13- The instruction seq(1,2,by=0.1) gives the following vector:
[1] 1.0 1.1 1.2 1.3 1.4 1.5 1.6 1.7 1.8 1.9 2.0

2.14- The instruction rep(1:3, each=2) gives the following vector:
1 1 2 2 3 3

2.15- The instruction rep(1:3, 2) gives the following vector:
1 2 3 1 2 3

2.16- Functions to enter data at hand in a small spread sheet are: data.entry() and de().

---

### Solutions to Exercises from Chapter 3

3.1- [1] 2 12
3.2- [,1] [,2]
   [1,] 1 1
   [2,] 2 2

3.3- Using functions rownames() and colnames().
3.4- cbind(X, Y)
3.5- For the product of all elements of a matrix X: prod(X).
   For the product of the elements of each column of matrix X:
   apply(X, FUN=prod, MARGIN=2).
3.6- [1] 4
   [1] 2 6 8 3
3.7- weight[height>180]
3.8- [1] 7 8 9
   [1] 5 6
3.9- L[[4]] <- 1:10
3.10- [1] 67
3.11- attach(X)
   weight[sex="F"]
   height[sex="F"]
# or:
X[sex=="F",-3]

3.12- [1] 1 2 3 and integer(0)
3.14- [1] 4 4
3.15- [1] "acbd"
3.16- [[1]]
       [1] "ab" "cd"
3.17- [1] "" "cd"
3.18- tolower(c("Jack","Julia","William"))
3.19- strftime().

---

### Solutions to Exercises from Chapter 4

4.1- help(mean).
4.2- This instruction provides a list of all functions whose name contains the searched word.
4.3- This instruction gives examples on using the searched function.
4.4- Command RSiteSearch() enables one to search one the web site http://search.r-project.org/nmz.html directly from R. The extracted information is then displayed in your browser.
4.5- 1. The header of the file, with:
    - the name of the function for which we are looking for help;
    - the name of the package in which the function is included (e.g.: base);
    - the origin of the help file: R Documentation;
  2. An explicit title for the function (e.g.: Arithmetic Mean).
  3. A brief description of what the function does: Description.
  4. How to use the function; in particular, the compulsory and optional arguments: Usage.
  5. A description of the function’s arguments: Arguments.
  7. References (statistical articles or books) related to the function’s application domain: References.
  8. The See Also section, which lists similar or related functions.
  9. Examples of use: Examples
4.6- help(package="stats") or library(help="stats").
4.7- Type data() to see a list of data sets and then type the name of the chosen data set.
Solutions to Exercises from Chapter 5

5.1- The \texttt{windows()} command is used to open a graphical device. The \texttt{dev.off()} command closes the window specified by \texttt{device-number} (if no device number is given, the active window is closed).

5.2- \texttt{savePlot(filename="myplot",type="pdf",device=dev.cur())}

5.3- The instruction \texttt{par(mfrow=c(3,2))} opens a graphical window where plots are successively displayed in a “matrix” with 3 rows and 2 columns (filled by rows).

5.4- Function \texttt{layout()} enables one to obtain a more evolved splitting of the graphical window than using function \texttt{par()}.

5.5- \texttt{points()}

5.6- \texttt{type="l"}

5.7- \texttt{abline()}

5.8- Function \texttt{curve()} enables one to draw any function of \texttt{x}.

5.9- The argument \texttt{col}.

5.10- Function \texttt{image()}. The instruction

\[
\text{image(as.matrix(rev(as.data.frame(t(X)))))}
\]

enables one to display coherently the image whose values are given in matrix \(X\).

5.11- Function \texttt{text()}.

5.12- Function \texttt{identify()} or \texttt{locator()}.

5.13- The instruction \texttt{par(ask=TRUE)} outputs a message asking the user to press the ENTER key before each new plot is drawn.

5.14- \texttt{lty}

5.15- \texttt{pch}

5.16- \texttt{curve(cos(x),xlim=c(-10,10),xlab="X axis",col="blue", main="Sinus and cosinus curves",ylim=c(-2,2),ylab="sin(x)")}
\texttt{curve(sin(x),add=TRUE)}
\texttt{abline(h=0,col="red")}
\texttt{abline(v=0,col="red")}
\texttt{arrows(3*pi/2,1,pi/2,1)}
\texttt{text((3*pi)/2,1,expression(hat(beta)[1]))}

Solutions to Exercises from Chapter 6

6.1- • \texttt{function(name) \{name\}}: the class of the returned R object is \texttt{function}, the display produced is: \texttt{function(name) \{name\}}.
• \(\text{(function(name) \{name\})\("Ben")}\): the class of the returned \textit{R} object is \texttt{character}, the display produced is: "Ben"
• \(\text{(function(name) \{cat(name,\"\n\")\})\("Ben")}\): the returned \textit{R} object has no class, the display produced is: Ben
• \(\text{(function(name) \{invisible(name)\})\("Ben")}\): the class of the returned \textit{R} object is \texttt{character}, no display.

6.2-  
• No difference.
• No difference.
• No difference.

6.3-  
• No difference when executing \texttt{name()} and \texttt{name("Peter")} if the function \texttt{name()} is defined by \texttt{name <- function(name="Peter") name} and also by \texttt{name <- function(name="Peter") name2 <- name}. For these two functions, the nature of \texttt{res}, obtained by \texttt{res <- name("Ben")} is of type \texttt{character}.

6.4- "Peter".

6.5-  
• "Ben L"
• "Ben L"
• "R D"

6.6- \texttt{name <- function(name="Peter") \{cat(name,\"\n\")\}}

6.7- For the execution of \texttt{names("peteR", "Ben", "R")}

• [1] "peteR" "Ben" "R"
• [[1]]
  [1] "peteR"

• [2]
  [1] "Ben"

• [3]
  [1] "R"

• [1] "peteR"
• [1] "Ben"
• [1] "R"

• [1] "peteR"
• [1] "Ben"
• [1] "R"

For the execution of \texttt{names(c("peteR", "L"), c("Ben", "L"), c("R", "D"))}

• [1] "peteR" "L" "Ben" "L" "R" "D"
• [[1]]
  [1] "peteR" "L"

• [2]
  [1] "Ben" "L"
[[3]]
[1] "R" "D"
• [1] "peteR"
  [1] "L"
  [1] "Ben"
  [1] "L"
  [1] "R"
  [1] "D"
• [1] "peteR" "L"
  [1] "Ben" "L"
  [1] "R" "D"
6.8- For the function
\[
\text{names} <- \text{function(names=c("Ben","R"),\ldots) c(names,\ldots)}
\]
• [1] "PeteR"
• [1] "PeteR"
• [1] "PeteR"
For the function
\[
\text{names}<-\text{function(\ldots, names=c("Ben","R") c(names,\ldots)}
\]
• [1] "Ben" "R" "PeteR"
• name
  "Ben" "R" "PeteR"
• [1] "PeteR"
6.9- Male <- function(firstname,name) {
  obj <- list(firstname=firstname,name=name)
  class(obj) <- "Male"
  obj
}
• hello.Male <- function(obj)
  cat("Hello Mister",obj$firstname,obj$name,"!
• Hello Mister Ben L !
• Error: impossible to find function "hello"
• hello <- function(obj) UseMethod("hello")
6.10- Female <- function(firstname,name) {
  obj <- list(firstname=firstname,name=name)
  class(obj) <- "Female"
  obj
}
• hello.Female <- function(obj)
  cat("Hello Mrs.",obj$firstname,obj$name,"!
• Hello Mister Elsa R !
• Hello Mrs. Elsa R !
• Hello Mrs. Elsa R !
6.11- Hello Mister Ben L !
Hello Mrs. Elsa R !
• Error in UseMethod("hello"):
  no method for 'hello' applicable for
an object of class "character"
• Hello Ben!
  Hello L!
  Hello Elsa!
  Hello R!

Solutions to Exercises from Chapter 7

7.1- ls() or objects().
7.2- rm(foo).
7.3- getwd().
7.4- setwd(choose.dir()).
7.5- Save in a file (name.RData) the objects that have been created.
7.6- The history of commands, the working environment, the contents displayed
in the console, and the graphs.
7.7- This allows you to recall and replay previously typed commands (using ar-
rows up and down on the keyboard).
7.8- The function history() displays in a new window the list of all previous
commands typed in the current session.
7.9- png(file="myplot.png")
  curve(x**2)
  dev.off()
7.10- It enables one to access variables of a data.frame directly by their name.
7.11- require() (or library())
7.12- Import a sequence of R instructions from a file to the console, and checks the
syntax.

Solutions to Exercises from Chapter 8

8.1- choose().
8.2- The instruction sum(1:n).
8.3- range().
8.4- The term by term product of the two following matrices:
LIST OF R PACKAGES MENTIONNED IN THE BOOK

[1,] [,2]
[1,] 1 0
[2,] 0 1

and

[,1] [,2]
[1,] 1 3
[2,] 2 4

which gives

[,1] [,2]
[1,] 1 0
[2,] 0 4

8.5- `%*%()
8.6- Function \texttt{solve()} for the inverse and function \texttt{t()} for the transpose.
8.7- The instruction \texttt{diag(5)}.
8.8- Command \texttt{det()} for the determinant and \texttt{sum(diag())} for the trace.
8.9- \texttt{scale(A)}.
8.10- Function \texttt{eigen()}.
8.11- \texttt{myf <- function(x) \{3*x^2+2\}}
      \hspace{1cm} \texttt{integrate(myf,lower=-1,upper=1)}

8.12- \texttt{optimize(f=function(x)(sin(x))^2,lower=0,upper=2,maximum=TRUE)}
8.13- Command \texttt{uniroot()} for a function and \texttt{polyroot()} for a polynomial.

\begin{center}
\textbf{Solutions to Exercises from Chapter 9}
\end{center}

9.1- \texttt{table(x)/length(x)}.
9.2- \texttt{table(x,y)}.
9.3- \texttt{margin.table()}.
9.4- \texttt{prop.table()}.
9.5- \texttt{names(which.max(table(mytable))}.
9.6- \texttt{diff(range(x))}.
9.7- \texttt{IQR(x)}.
9.8- \texttt{var(x)*(length(x)-1)/length(x)}.
9.9- \texttt{sqrt(var(x)*(length(x)-1)/length(x)/mean(x))}.
9.10- \texttt{mean(abs(x-mean(x)))}.
9.11- Package moments.
9.12- First, we need to compute the $\chi^2$ statistic using:
      \begin{verbatim}
      chi2 <- summary(table(mytable))$statistic
      \end{verbatim}
Cramér's $\Phi^2$ is obtained by $\chi^2 / N$.

9.13- Here is the code to compute the correlation ratio $\eta^2_{\text{IV}}$:

```r
eta2 <- function(x,gp) {
  means <- tapply(x,gp,mean)
  frequency <- tapply(x,gp,length)
  varinter <- (sum(frequency * (means - mean(x))^2))
  vartot <- (var(x) * (length(x) - 1))
  res <- varinter/vartot
  return(res)
}
```

9.14- Function `barplot()` can be used to obtain a Pareto diagram.

9.15- A stacked bar chart can be obtained using the function `barplot()` with an object of type `matrix` as first argument.

9.16- Function `pie()` can be used to obtain a pie chart.

9.17- Function `boxplot()` can be used to obtain a box plot.

9.18- Function `hist()` is used to draw a histogram.

### Solutions to Exercises from Chapter 10

10.1- `rnorm()`.

10.2- `rnorm(n,mean=2,sd=sqrt(10))` generates $n$ realizations of a random variable with $\mathcal{N}(2, 10)$ distribution.

10.3- `qchisq()`.

10.4- `df()`.

10.5- `qt()`.

10.6- `pnorm(5,mean=2,sd=sqrt(2))-pnorm(3,mean=2,sd=sqrt(2))`

10.7- `qnorm(0.95)`

### Solutions to Exercises from Chapter 11

11.1- `qbinom()`.

11.2- Function `pnorm()` is used to compute the Gaussian cumulative distribution function.

11.3- `t.test(x,conf.level=0.9)$conf.int`

11.4- Function `prop.test()` is used to compute a confidence interval for a proportion or to perform a statistical test for a proportion by approximating the bino-
mial distribution by a normal distribution, whereas function `binom.test()` performs exact computations.

11.5- `ks.test()` and `wilcox.test()`.
11.6- `shapiro.test()`.
11.7- `chisq.test()` and `fisher.test()`.
11.8- Package `boot`.
11.9- `paired=TRUE`.
11.10- The $\chi^2$ test of independence enables one to test the dependence between two qualitative variables whereas the $\chi^2$ goodness-of-fit test can be used to test if a qualitative variable follows a given distribution. To perform these two tests, you can use the `chisq.test()` function. The $\chi^2$ test of independence is performed on a table. For the $\chi^2$ goodness-of-fit test, it is necessary to specify the `p` argument representing the theoretical probabilities of the possible outcomes of the qualitative variable.

### Solutions to Exercises from Chapter 12

12.1- `lm(Y~X1)`.
12.2- `lm(Y~X1-1)` or `lm(Y~0+X1)`.
12.3- `lm(Y~X1+X2)`.
12.4- `lm(Y~X1+X2+X1:X2)` or `lm(Y~X1*X2)`.
12.5- `lm(Y~X1+I(X1^2)+I(X1^4))`.
12.6- `anova(lm(Y~X1+X2), lm(Y~X1+X2+X3+X4))`.
12.7- `residuals()`.
12.8- `coefficients()`.
12.9- The variable $Z$ has to be introduced as a factor by means of the `factor()` command.
12.10- `lm(Y~poly(X,3))`.
12.11- `add1()`.
12.12- `drop1()`.

### Solutions to Exercises from Chapter 13

13.1- `aov(Y~factor(A))`.
13.2- `aov(Y~factor(A)+factor(B))`.
13.3- `aov(Y~factor(A)*factor(B))`.
13.4- `bartlett.test()` and `levene.test()`.
13.5- `pairwise.t.test()`.
13.6- `summary(lm(Y~factor(X)))`.
13.7- The function `C()`.
Solutions to Worksheet

Study of Body Mass Index

1.1- Individuals <- c("Edward","Cynthia","Eugene","Elizabeth",
"Patrick","John","Albert","Lawrence","Joseph","Leo")
Weight <- c(16,14,13.5,15.4,16.5,16,17,14.8,17,16.7)
Height <- c(100,97,95.5,101,100,98.5,103,98,101.5,100)
Gender <- c("F","F","M","F","M","M","M","M","M","M")

1.2- mean(Weight) # result : [1] 15.69
mean(Height) # result : [1] 99.45

1.3- BMI <- Weight/(Height/100)^2
BMI # Outputs the results.

1.4- myTable <- data.frame(Individuals,Weight,Height,Gender,BMI)
myTable # Outputs the results.

1.5- help(plot)

1.6- plot(Height,Weight,main="Scatter plot of Weight as a function of Height")

Solutions to Worksheet from Chapter 2

Reading various data sets
A- Entering data from a hard copy

• Fever blisters

2.1- `blisters <- as.data.frame(de(''))`

First, change the type of each column to Real, and the names to `trti.1 ≤ i ≤ 5` (by clicking on the first cell of each column), then enter your data. Click on Quit at the end. Next, we can type the following command to display the data in R:

    blisters # Outputs the data.

2.2- `attach(blisters)`

    mean(trt1) # Result: [1] 7.5
    mean(trt2) # Result: [1] 5
    mean(trt3) # Result: [1] 4.333333
    mean(trt4) # Result: [1] 5.166667
    mean(trt5) # Result: [1] 6.166667

2.3- We obtain directly the same results by typing:

    `colMeans(blisters)`

2.4- `write.table(file="blisters.txt",blisters,row.names=FALSE)`

2.5- You can use your favorite text editor to display the contents of the file `blisters.txt` and thus check if it has been correctly created (the instruction `getwd()` will tell you where this file has been saved).

2.6- `ls()`

    rm(blisters)

    ls()

    blisters # We see that the object blisters has disapeared.

2.7- `blisters <- read.table("blisters.txt",header=TRUE,sep="")`

    blisters # Here is is again!

• Risk factors for atherosclerosis

2.1- Enter data as they are organized in the contingency table, by pressing the ENTER key after each end of line. After the last line, press once more on the ENTER key.

    `X <- scan()` # Data are then collected in a vector.
    `X <- matrix(X,ncol=3,nrow=6,byrow=TRUE)`

2.2- `class(X) <- "ftable"`
2.3- attributes(X)$col.vars<-list(alcohol=c("nondrinker","occasional-drinker","regular-drinker"))
    attributes(X)$row.vars<-list(GENDER=c("M","F"),tobacco=c("non-smoker","former smoker","smoker"))

2.4- X

2.5- write.ftable(X,file="athero.txt")

2.6- You can use your favorite text editor to display the contents of the file athero.txt and thus check that it has been correctly created (the instruction getwd() will tell you where this file has been saved).

2.7- rm(X)
    X # The object has been removed.

2.8- X <- read.ftable(file="athero.txt")
    X # Here it is again!

B- Importing from other software

2.1- You can begin by downloading the file http://biostatisticien.eu/springeR/bmichild.xls using your browser. If you have Excel, you can then transform it into the file bmichild.txt, with TAB as separators, then use the following R command:

    bmi.XLS <- read.table(file.choose(),header=TRUE,sep="\t",dec="\",)

If you do not have Excel, you can use the package xlsReadWrite, after installing it:

    require(xlsReadWrite)
    bmi.XLS <- read.xls("bmichild.xls")

Finally, under Linux, you can use the commands:

    require(gdata)
    bmi.XLS <- read.xls("http://biostatisticien.eu/springeR/bmichild.xls")

2.2- Install the package foreign. Download the file http://www.biostatisticien.eu/springeR/bmichild.xpt using your browser.

    require(foreign)
    bmi.SAS <- read.xport(file.choose()) # Select bmichild.xpt.

2.3- url <- "http://www.biostatisticien.eu/springeR/bmichild.sav"
    bmi.SPSS <- read.spss(url)
    bmi.SPSS <- as.data.frame(bmi.SPSS)

2.4- Install the package R.matlab.
require(R.matlab)
x <- readMat("http://www.biostatisticien.eu/springerR/bmichild.mat")
class(x) # x is a list.
x # We see that the data are in $bmi[,,1]$.
x <- x$bmi[,,1]
# Note that the elements of GENDER and zep are saved into a list.
x$GENDER
class(x$GENDER) <- "character"
x$GENDER
class(x$zep) <- "character"
bmi.MAT <- as.data.frame(x)

2.5- summary(bmi.XLS)
   summary(bmi.SAS)
   summary(bmi.SPSS)
   summary(bmi.MAT)

2.6- write.table(bmi.SPSS,"bmichild.txt",row.names=FALSE)

C- Importing more complex data files

2.1- readLines("http://biostatisticien.eu/springerR/geoidformat.txt")
    X <- scan("http://biostatisticien.eu/springerR/raf98.gra",skip=3)
    X <- matrix(X,ncol=421,nrow=381,byrow=TRUE)
    dim(X)

2.2- Save the file http://biostatisticien.eu/springerR/Infarction.xls using your browser,
    then transform it into a file Infarction.txt (TAB as separator). Next, use the
    command:

    infarction <- read.table("Infarction.txt",header=TRUE,sep="\t",
                            na.strings = ",",dec=".")

    Under Linux, rather use:

    require(gdata)
    url <- "http://biostatisticien.eu/springerR/Infarction.xls"
    infarction <- read.xls(url,header=TRUE,sep="","na.strings=","+dec=".

2.3- Download the file http://biostatisticien.eu/springerR/nutrition_elderly.txt
    in the folder whose name is given by the command getwd(),
    then enter the following commands:

    X <- read.table("nutrition_elderly.txt",row.names=1)
    X <- t(X)
    X <- as.data.frame(X)
url <- "http://www.biostatisticien.eu/springeR/Birth_weight.txt"
readLines(url) # To get an idea of the file organization.
# Note the three missing lines [33] to [35],
# and also the presence of dashes at line [194].
X <- read.table(url,row.names=1,skip=1,header=FALSE,sep=";",nrows=189,
    blank.lines.skip=TRUE)
Y <- read.table(url,nrows=1,row.names=1)
colnames(X) <- as.matrix(Y)
head(X) # Display the first lines of X.
Manipulating various data sets

A- Manipulating a few data sets presented at the beginning of the book

File nutrielderly.xls

3.1- Install the package gdata. Be careful that the use of this package necessi-
tates the PERL software which is not available by default under Windows. Thus install also PERL (http://www.biostatisticien.eu/springeR/Rtools.exe).

```r
require(gdata)
nutrien1 <- read.xls("http://www.biostatisticien.eu/springeR/nutrien1.xls")
nutrien2 <- read.xls("http://www.biostatisticien.eu/springeR/nutrien2.xls")
colnames(nutrien1) <- tolower(colnames(nutrien1))
result <- rbind(nutrien1,nutrien2)
```

3.2- nutrien3 <- read.xls("http://www.biostatisticien.eu/springeR/nutrien3.xls")
nutrien4 <- read.xls("http://www.biostatisticien.eu/springeR/nutrien4.xls")
result <- merge(nutrien3,nutrien4,all=TRUE)

3.3- nutrien5 <- read.xls("http://www.biostatisticien.eu/springeR/nutrien5.xls")
nutrien6 <- read.xls("http://www.biostatisticien.eu/springeR/nutrien6.xls")

The coding of the variables is given in the table in section B.4. We will try to identify abnormal values using the following instruction:

```r
apply(nutrien5,FUN=table,MARGIN=2)
```

We can identify six abnormal values in nutrien5: gender=12, gender=21, height=1.67, weight=200, age=8 and chocol=7. The subjects with these abnormal values are identified using:

```r
ind5gender <- nutrien5$Subject[which(nutrien5$gender %in% c(12,21))]
ind5height <- nutrien5$Subject[which(nutrien5$height==1.67)]
ind5weight <- nutrien5$Subject[which(nutrien5$weight==200)]
ind5age <- nutrien5$Subject[which(nutrien5$age==8)]
ind5chocol <- nutrien5$Subject[which(nutrien5$chocol==7)]
ind5abnorm <- c(ind5gender,ind5height,ind5weight,ind5age,ind5chocol)
```

Let us do the same with nutrien6.

```r
apply(nutrien6,FUN=table,MARGIN=2)
```
We find seven abnormal values in `nutrien6`:
gender=12, gender=21, weight=8, age=7, meat=6, chocol=6, and fat=9. The subjects with these abnormal values are identified using:

```r
ind6gender <- nutrien6$Subject[which(nutrien6$gender %in% c(12,21))]
ind6weight <- nutrien6$Subject[which(nutrien6$weight==8)]
ind6age <- nutrien6$Subject[which(nutrien6$age==7)]
ind6meat <- nutrien6$Subject[which(nutrien6$meat==6)]
ind6chocol <- nutrien6$Subject[which(nutrien6$chocol==6)]
ind6fat <- nutrien6$Subject[which(nutrien6$fat==9)]
ind6abnorm <- c(ind6gender,ind6weight,ind6age,ind6meat,ind6chocol,ind6fat)
```

We will now look at whether it is possible to correct some of these abnormal values. To do this, we will investigate whether an individual with an abnormal value in one of the tables may be present in another table with a normal value. Here is the list of common subjects between both files:

```r
ind.com <- intersect(nutrien6$Subject,nutrien5$Subject)
```

List of abnormal subjects in `nutrien5` that are also present in `nutrien6`:

```r
intersect(ind.com,ind5abnorm)
# Result : no subject.
```

List of abnormal subjects in `nutrien6` that are also present in `nutrien5`:

```r
intersect(ind.com,ind6abnorm)
# Result: subject 30
nutrien5[nutrien5$Subject==30,]
nutrien6[nutrien6$Subject==30,]
# We have gender=21 in nutrien6 and gender=2 in nutrien5.
```

We thus replace this value in `nutrien6`:

```r
nutrien6$gender[which(nutrien6$Subject==30)] <- nutrien5$gender[which(nutrien5$Subject==30)]
```

We can now merge the two tables:

```r
result <- merge(nutrien5,nutrien6,all=TRUE)
```

Without other information on abnormal data, we decide not to change them for the moment.

3.4- `nutrien7` <- read.xls("http://www.biostatisticien.eu/springeR/nutrien7.xls")
`nutrien8` <- read.xls("http://www.biostatisticien.eu/springeR/nutrien8.xls")
result <- cbind(nutrien7,nutrien8)

3.5- `nutrien9` <- read.xls("http://www.biostatisticien.eu/springeR/nutrien9.xls")
`nutrien10` <- read.xls("http://www.biostatisticien.eu/springeR/nutrien10.xls")
apply(nutrien9,FUN=table,MARGIN=2,useNA="ifany")
apply(nutrien10,FUN=table,MARGIN=2,useNA="ifany")
The variable `chocol` contains 29 missing data points. We delete this variable before combining the two tables:

```r
nutrien9bis <- nutrien9[, -which(colnames(nutrien9) == "chocol")]
result <- cbind(nutrien9bis, nutrien10)
```

3.6- nutrien11 <- read.xls("http://www.biostatisticien.eu/springeR/nutrien11.xls")
nutrien12 <- read.xls("http://www.biostatisticien.eu/springeR/nutrien12.xls")
# Number of missing values for all individuals in each table:
ind11NA <- apply(is.na(nutrien11), FUN=sum, MARGIN=1)
ind12NA <- apply(is.na(nutrien12), FUN=sum, MARGIN=1)
# Determination of the individual with the most missing values:
ind11max <- which.max(ind11NA)  # We find the individual 86.
ind12max <- which.max(ind12NA)  # We find the individual 86.
ind11NA[ind11max]  # 3 missing values.
ind12NA[ind12max]  # 4 missing values.

The individual 86 has 7 missing values on 13 variables. We suppress it from the merged table:

```r
result <- cbind(nutrien11, nutrien12)[-86,]
```

3.7- url <- "http://www.biostatisticien.eu/springeR/nutri_elderly.xls"
nutri_elderly <- read.xls(url)
nrow(nutri_elderly[nutri_elderly$fish == 0 & nutri_elderly$meat == 0,])

There is no vegetarian among the individuals studied.

File `Intima_Media_Thickness.xls`

Intima <- read.xls()
Intima <- transform(Intima, BMI = weight / (height/100) ^ 2)
# or equivalently:
# BMI <- Intima$weight / ((Intima$height/100) ^ 2)
# Intima <- cbind(Intima, BMI)
3.2- Intima$measure[Intima$BMI > 30]
3.3- Intima[Intima$SPORT == 1,]
3.4- Intima[Intima$BMI <= 30 & Intima$AGE >= 50,]

File `bmichild.xls`

3.1- bmichild <- read.xls("http://www.biostatisticien.eu/springeR/bmichild.xls")
bmichild <- transform(bmichild, BMI = weight / (height/100) ^ 2)
# or equivalently:
# BMI <- bmichild$weight/((bmichild$height/100)^2)
# bmichild <- cbind(bmichild,BMI)

3.2- subset(bmichild,BMI<15 & an<=3.5 & month <=5)  # or equivalently:
# or equivalently:
# bmichild[bmichild$BMI<15 & bmichild$an <=3 & bmichild$month<=5,]

3.3- sum(bmichild$BMI<15 & bmichild$an<=3 & bmichild$month<=5)  # or equivalently:
# or equivalently:
# nrow(bmichild[bmichild$BMI<15 & bmichild$an<=3 & bmichild$month<=5,])

We find 7 children.

File Birth_weight.xls

3.1- url <- "http://www.biostatisticien.eu/springeR/Birth_weight.xls"
birth.weight <- read.xls(url)  
PTL1 <- birth.weight$PTL  
PTL1[birth.weight$PTL>=2] <- 2  
birth.weight <- cbind(birth.weight,PTL1)

3.2- FVT1 <- birth.weight$FVT  
FVT1[birth.weight$FVT>=2] <- 2  
birth.weight <- cbind(birth.weight,FVT1)

3.3- birth.weight[order(birth.weight$BWT),]

3.4- birth.weight[birth.weight$RACE<=2 & birth.weight$SMOKE==1,]

B- Handling missing values

Install the package gdata. And since this package necessitates PERL, also install PERL (http://www.biostatisticien.eu/springeR/Rtools.exe). Now, we read the data:

url <- "http://www.biostatisticien.eu/springeR/Infarction.xls"
read.xls(url)

We note that the missing values are coded with ".". We thus use the following instruction:

infarction <- read.xls(url,na.strings=".")

3.1- indNA <- which(apply(is.na(infarction),FUN=any,MARGIN=1)==TRUE)
3.2- sup1 <- function(x) {sum(x)>1}
    indNA <- which(apply(is.na(infarction),FUN=sup1,MARGIN=1)==TRUE)
    infarction$NUMBER[indNA]

3.3- colnames(infarction)[which(apply(is.na(infarction),FUN=any,MARGIN=2)==TRUE)]

3.4- a) infarction[as.logical(apply(!is.na(infarction),1,prod)),]
    b) infarction[(apply(infarction,1,is.na),2,any),]
    c) infarction[(apply(infarction,1,is.na),2,all),]
    d) infarction[complete.cases(infarction),]
    e) na.omit(infarction)

C- Handling character strings

3.1- url <- "http://www.biostatisticien.eu/springeR/dept-pop.csv"
    dept <- read.csv(url,dec="","")

3.2- numdep <- substring(dept$Departement,1,3)
    Dept <- substring(dept$Departement,4)
    dept <- cbind(numdep,Dept,dept[-1])

D- Influenza epidemics in France since 1984

3.1- url <- "http://www.biostatisticien.eu/springeR/flu.csv"
    head(read.csv(url))
    We note that the missing values are coded using dashes (-). We thus use the
    following instruction:
    flu <- read.csv(url,na.strings="-")

3.2- names(flu)
    flu$Date

3.3- unique(sort(substring(flu$Date,5,6)))
    We find the numbers "01" to "53".

3.4- strptime("198444",format="%Y%W")
    We notice that the above instruction gives the correct year, but in fact the
    current day and month.

3.5- We read on the calendar that the first monday of the 44th week corresponds
    to october 29, 1984.

3.6- strptime("1984441",format="%Y\%W\%w")

3.7- flu$Date[1:10]
    strftime(paste(as.character(flu$Date[1:10]),"1",sep=""),format="%Y\%W\%w")
We notice on the website calendar that this does not work for December 31, 1984. We should rather use:

```r
strptime("1984531",format="%Y%W%w")
```

whereas we used:

```r
strptime("1985011",format="%Y%W%w")
```

Thus there is a problem with week format.

```r
date1 <- as.POSIXlt("29,10,1984",format="%d,%m,%Y")
date1

date1+7
```

The above operation added 7 seconds to `date1`.

```r
date1+7*24*60*60
```

```r
dates <- date1 + 7*24*60*60*(0:(nrow(flu)-1))
```

```r
mask1 <- (as.POSIXlt(dates) >= as.POSIXlt("1992-09-15"))
mask2 <- (as.POSIXlt(dates) <= as.POSIXlt("1993-11-03"))
portion <- flu[mask1 & mask2,]
```

```r
flu.cases <- colSums(portion[,1],na.rm=TRUE)
```

### E- Combining tables or lists; other manipulations

```r
a <- matrix(1:6,3,2)
rownames(a) <- c(1,2,6)
b <- matrix(1:8,4,2)
rownames(b) <- c(3,4,5,7)
```

```r
ab <- rbind(a,b)
ab <- ab[order(rownames(ab)),]
ab
```

```r
list1 <- list()
list1[[1]] <- matrix(runif(25),nr=5)
list1[[2]] <- matrix(runif(30),nr=5)
list1[[3]] <- matrix(runif(15),nr=5)
```

```r
matrix(unlist(list1),nrow=5)
# or also:
do.call(cbind,list1)
```
3.4- list2 <- list()
  list2[[1]] <- matrix(runif(25),nc=5)
  list2[[2]] <- matrix(runif(35),nc=5)
  list2[[3]] <- matrix(runif(15),nc=5)

  tmp <- lapply(list2,FUN=t)
  t(matrix(unlist(tmp),nrow=5))
  # or also:
  do.call(rbind,list2)

3.5- tmp <- data.frame(Disease = c("Infarction", "Hepatitis", "Lung cancer"),RF = c("tobacco, alcohol", "alcohol", "tobacco"))
  tmp
  tmp$Disease[grep("tobacco",tmp$RF)]

F- The French chevalier de Méré

- fourthrows <- function() {
    asixormore <- 0
    game <- sample(1:6,4,replace=TRUE)
    nbsix <- sum(game == 6)
    if(nbsix >= 1) asixormore <- 1
    return(asixormore)
  }

- twentyfourthrows <- function() {
    adoublesixormore <- 0
    die1 <- sample(1:6,24,replace=TRUE)
    die2 <- sample(1:6,24,replace=TRUE)
    nbdoublesix <- sum(die1[which(die1 == die2)] == 6)
    if(nbdoublesix >= 1) adoublesixormore <- 1
    return(adoublesixormore)
  }

- meresix <- function(nsim = 2000) {
    atleastsix <- 0
    atleatadoublesix <- 0
    for (j in 1:nsim) {
      atleastsix <- atleastsix + fourthrows()
      atleatadoublesix <- atleatadoublesix + twentyfourthrows()
    }

    #************* Displaying the output ***************
    cat("Frequency of 6s =",atleastsix/2000,"\n")
    cat("Frequency of double-6s =",atleastadoublesix/2000,"\n")
  }
Solutions to Worksheet from Chapter 4

Where to find information

4.1- We type
  
  help.search("combination")
  
  then we note the right function. We choose the one from package utils
  which is present by default in R.
  
  help(combn)

4.2- combn(c(5,8,2,9),3)

4.3- help.search("crime")
  
  help(USArrests)

4.4- dim(USArrests)     # Dimension of the data set.
  
  names(USArrests)      # Names of variables.
  
  rownames(USArrests)   # Names of individuals (states).

4.5- Subscribe to: https://stat.ethz.ch/mailman/listinfo/r-help

4.6- Read the General Instructions on the R Mailing Lists page and the posting
  guide on http://www.r-project.org/posting-guide.html

4.7- To unsubscribe, it suffices to follow the instructions given at the bottom of
  page https://stat.ethz.ch/mailman/listinfo/r-help

4.8- Connect on IRC, for example via the web site http://webchat.freenode.net

4.9- Subscribe to http://forums.cirad.fr/logiciel-R/index.php TO BE

4.10- Read the Windows FAQ from http://cran.r-project.org/faqs.html.
  
  Section 5.5 explains TAB completion mechanism.

4.11- Enter a quote (") then press twice on the TAB key.

Solutions to Worksheet from Chapter 5

Creating various plots

A- Complex numbers
598

LIST OF R PACKAGES MENTIONNED IN THE BOOK

5.1- z <- 1+2i
plot(1,3,xlab="Re(z)",ylab="Im(z)",xlim=c(0,2.5),ylim=c(0,2.5),
main="Complex numbers")
segments(0,0,Re(z),Im(z))
points(Re(z),Im(z),pch=19)
abline(h=0,v=0)
segments(Re(z),0,Re(z),Im(z),lty=3)
segments(0,Im(z),Re(z),Im(z),lty=3)
text(Re(z),Im(z),"z",pos=4)
text(0.4,1.1,"Mod(z)",srt=Arg(z)*180/pi)
r<-0.5
x<-seq(from=Re(r*exp(1i*Arg(z))),to=r,length=100)
y<-sqrt(0.5ˆ2-xˆ2)
points(x,y,type="l")
text(0.55,0.35,"Arg(z)",srt=-45,cex=0.8)
B- Flag of Canada
5.1- require(caTools)
5.2- Save the file http://www.biostatisticien.eu/springeR/canada.gif
in your working environment. Then launch the instruction:
X <- read.gif("canada.gif")
5.3- image(as.matrix(rev(as.data.frame(t(X$image)))),col=X$col)
5.4- coord <- locator(25) # Retrieve coordinates of points
# constitutive of the contour maple leaf.
rec1 <- locator(2)
# Retrieve coordinates of bottom-left and
# top-right vertices of left rectangle.
rec2 <- locator(2)
# Retrieve coordinates of bottom-left and
# top-right vertices of right rectangle.
windows() # or X11() under Linux.
plot(0,xlim=c(0,1),ylim=c(0,1),type="n",ann=FALSE,axes=FALSE)
rect(rec1$x[1],rec1$y[1],rec1$x[2],rec1$y[2],col="red")
rect(rec2$x[1],rec2$y[1],rec2$x[2],rec2$y[2],col="red")
polygon(coord,col="red")
C- Frequency tables
5.1- Enter the data set:
X <- matrix(c(1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,1,1,1,1,1,
1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,1,2,1,1,1,1,1,1,1,1,


For this, create a function:

```r
f <- function(x){
  fi <- tabulate(x,4)/16
  as.vector(t(cbind(fi,1-fi)))
}
```

5.2- `freq <- apply(X[,,-1],FUN=f,MARGIN=2)`

5.3- `barplot(freq,col=c("black","white"))`

5.4- `windows()` # or X11() under Linux.

D- Anatomic images of the brain

5.1- Read the data:

```r
dim <- 256
url <- "http://www.biostatisticien.eu/springeR/anat.img"
bytes <- readBin(url,what="raw",n=dim*dim*2)
```

5.2- Permute pairs of bytes:

```r
nbval <- dim^2
indices <- rbind((1:nbval)*2,(1:nbval)*2-1)
indices <- as.numeric(indices)
x <- bytes[indices]
```

5.3- Transformation to decimal representation:

```r
x <- matrix(x,ncol=2,byrow=TRUE)
test <- function(x) {
  as.numeric(paste("0x",paste(x,collapse=""),sep=""))
}
values <- apply(x, MARGIN=1, FUN=test)

5.4- X <- matrix(values, nrow=dim, ncol=dim)

5.5- image(X, col=gray(0:100 / 100))

5.6- Install the package AnalyzeFMRI. Download the files anat.img and anat.hdr to your workspace, then type the following instructions:

require(AnalyzeFMRI)
Y <- f.read.volume("anat.img")
image(Y[,1], col=gray(0:1000 / 1000))

E- Drawing the map of a region of France

5.1- Install the packages maps and mapdata, then load them into memory:

require(maps)
require(mapdata)

5.2- map("france")

5.3- france <- map("france", plot=FALSE)

5.4- Latitude/longitude data are organized in france$x/france$y for each region in france$names (until the next NA).

5.5- Vector of NA indices:

indNA <- which(is.na(france$x))

5.6- deptname <- "Gard"

5.7- inddept <- which(france$names==deptname)

5.8- plot(france$x[indNA[inddept-1]:indNA[inddept]],
          france$y[indNA[inddept-1]:indNA[inddept]],
          type="l", main=deptname, xlab="Longitude", ylab="Latitude")

5.9- Retrieve coordinates of the town called Alès on http://www.gpsvisualizer.com/geocode.

ales <- c(4.08268, 44.121288)
points(ales[1], ales[2], pch=16, col="red")
text(ales[1], ales[2], "Alès", pos=1)

F- Representation of the geoid in France

5.1- Read the data:
LIST OF R PACKAGES MENTIONNED IN THE BOOK

5.2- Z <- matrix(data,nrow=421,ncol=381,byrow=FALSE)
Z <- as.matrix(rev(as.data.frame(Z)))
layout(mat=matrix(1:2,ncol=2),widths=c(5,1))
par(mar=c(4,4,3,0),mai=c(1, 1, 1, 0),las=1,tck=-0.01)
x<-seq(from=-5.5,to=8.5,length=421)
y<-seq(from=42,to=51.5,length=381)
image(x,y,Z,col=rainbow(17),xlab="Longitude",ylab="Latitude",axes=FALSE)
par(ps=18)
title("The quasigeoid QGF98 model",family="HersheyScript")
par(ps=11)
axis(1,at=(-6):8,labels=paste((-6):8,"o",sep=""))
axis(2,at=42:51,labels=paste(42:51,"o",sep=""))
contour(x,y,Z,add=TRUE)
par(mai=c(0, 0, 0, 0),bty="n")
plot(0:1,0:1,axes=FALSE,xlab="",ylab="",type="n")
legend("center",legend=42:55,fill=rainbow(17),bty="n",title="Meters")

Solutions to Worksheet from Chapter 6

Programming functions and object-oriented programming in R

A- Managing a bank account

6.1- .folder.accounts <- "./Account"
  path.account <- function(name) {
    file.path(.folder.accounts,paste(name,".RData",sep=""))
  }

6.2- account <- function(name) {
  path <- path.account(name)
  account <- data.frame(amount=numeric(0),
                        mode=factor(levels=c("Debit","Credit")),
                        date=character(0),remark=character(0))
  save(account,file=path)
  cat("Account",name,"created !\n")
}

6.3- debit <- function(name,amount,remark="",
  date=format(Sys.time(),"%d/%m/%Y") {
6.4- The instruction

\[ \text{sum(account[account$mode=="Credit","amount"])} \]

returns the credited amount on the account. We modify the function `account()` this way:

```r
account <- function(name) {
  if(!file.exists(path)) {
    account <- data.frame(amount=numeric(0),mode=factor(levels=c("Debit","Credit")),
                          date=character(0),
                          remark=character(0))
    save(account,file=path)
    cat("Account",name,"created !\n")
  } else {
    load(path)
    cat("State of account",name,"=",
        sum(account[account$mode=="Credit","amount"])
        - sum(account[account$mode=="Debit","amount"]),"euros.\n")
  }
}
```

B- Organizing graphical objects

6.1- Window <- function(x=0,y=0,width=2,height=2,log="") {
  obj <- list(x=x,y=y,width=width,height=height,log=log)
  class(obj) <- "Window"
  obj
}
6.2- Circle <- function(x=0,y=0, radius=0.5) {
    circle <- list(x=x,y=y, radius=radius)
    class(circle) <- "Circle"
    circle
}

Rectangle <- function(x=0,y=0, width=1, height=height) {
    rectangle <- list(x=x,y=y, width=width, height=height)
    class(rectangle) <- "Rectangle"
    rectangle
}

6.3- plot.Window <- function(obj) {
    plot.new()
    plot.window(xlim=obj$x+c(-1,1)*obj$width/2,
                ylim=obj$y+c(-1,1)*obj$height/2, obj$log, asp=1)
}

plot.Rectangle <- function(rectangle) {
    rect(rectangle$x-rectangle$width/2,rectangle$y-rectangle$height/2,
         rectangle$x+rectangle$width/2,rectangle$y+rectangle$height/2)
}

plot.Circle <- function(circle) {
    symbols(circle$x,circle$y,circle=circle$radius,inches=FALSE, add=TRUE)
}

6.4- mywindow <- Window(0,0,2,2)
mycircle <- Circle(0,0,.5)
myrectangle <- Rectangle(0,0,1,1)
plot(mywindow);plot(mycircle);plot(myrectangle)

6.5- MyPlot <- function(x=0,y=0, width=2, height=2, log="") {
    graph <- list(objets=list())
    class(graph) <- "MyPlot"
    graph
}

6.6- add.MyPlot <- function(graph,...) {
    graph$objects <- c(graph$objects, list(...))
    graph
}

add <- function(obj,...) UseMethod("add")

plot.MyPlot <- function(graph) {
    for(object in graph$objects) {
        ...
6.7- `MyPlot` <- function(..., x=0, y=0, width=2, height=2, log="") {
  graph <- list(objets=list())
  class(graph) <- "MyPlot"
  graph <- add(graph, Window(x, y, width, height, log), ...)
  graph
}

graph <- MyPlot(Circle(), Rectangle())
plot(graph)

6.8- `display` <- function(obj, ...) UseMethod("plot")
  graph <- MyPlot(Circle(), Rectangle())
  display(graph)

6.9- Your turn to play!

C- Creating a class `lm2` for linear regression with two regressors

```r
lm2 <- function(...) {
  obj <- lm(...)
  if(ncol(model.frame(obj))!=3)
    stop("two independent variables are required!")
  class(obj) <- c("lm2",class(obj)) # or c("lm2","lm")
  obj
}
```

```r
n <- 20
x1 <- runif(n,-5,5)
x2 <- runif(n,-50,50)
y <- .3+2*x1+2*x2+rnorm(n,0,20)
reg2 <- lm2(y~x1+x2)
summary(reg2)
```

```r
plot3d.lm2 <- function(obj, radius=1, lines=TRUE, windowRect, ...)
  {matreg <- model.frame(obj)
   colnames(matreg) <- c("y","x1","x2")
  }
```
LIST OF R PACKAGES MENTIONNED IN THE BOOK

```r
predlim <- cbind(c(range(matreg[,2]),rev(range(matreg[,2]))),
    rep(range(matreg[,3]),c(2,2)))
predlim <- cbind(predlim,apply(predlim,1, 
    function(l) sum(c(1,l)*coef(obj))
))
if(missing(windowRect)) windowRect=c(2,2,500,500)
open3d(windowRect=windowRect,...)
bg3d(color = "gray")
plot3d(formula(obj),type="n")
spheres3d(formula(obj),radius=radius,specular="green")
quads3d(predlim,color="blue",alpha=0.7,shininess=128)
quads3d(predlim,color="cyan",size=5,front="lines",back="lines",lit=F)
if(lines) {
    matpred <- cbind(matreg[2:3],model.matrix(obj)%*%coef(obj))
    points3d(matpred)
    colnames(matpred) <- c("x1","x2","y")
    matlines <- rbind(matreg[,c(2:3,1)],matpred)
    nr <- nrow(matreg)
    matlines <- matlines[rep(1:nr,rep(2,nr))+c(0,nr),]
    segments3d(matlines)
}
}
require(rgl)
plot3d(reg2)
rgl.snapshot("lm2vue1.png")
par3d(userMatrix=rotate3d(par3d("userMatrix"),-pi*.1, 0, 0, 1))
rgl.close()
```

**Solutions to Worksheet from Chapter 7**

Managing and creating packages

**A- Using the functions `attach()` and `detach()`**

7.2- Install the package `gdata`. Since this package necessitates PERL, install also PERL ([http://www.biostatisticien.eu/springeR/Rtools.exe](http://www.biostatisticien.eu/springeR/Rtools.exe)).
require(gdata)
bmichild <- read.xls("bmichild.xls")
names(bmichild)

7.3- When you type `GENDER`, R answers *Error: object 'GENDER' not found.*
7.4- When you type `ls()`, you cannot see the variable `GENDER`.
7.5- `attach(bmichild)`
    `GENDER`
    The contents of object `GENDER` appears.
7.6- The variable `GENDER` is still not visible with the instruction `ls()`.
7.7- `search()`
    We notice that the object `bmichild` appears in position 2.
7.8- `ls(pos=2)`
7.9- `detach(bmichild)`
    `search()`
    `GENDER`
7.10- `GENDER <- "Male"`
    `GENDER`
7.11- `attach(bmichild)`
        A warning message displays.
    `GENDER`
    It is "Male" that displays but not the contents of the object `GENDER` from the
    *data.frame*.
7.12- `GENDER # does not display the contents of the object`
    `# GENDER from the data.frame.`
    `weight`
7.13- `ls() # bmichild and GENDER are present.`
    `search() # bmichild is present.`
7.14- `ls(pos=2)`
7.15- `get("GENDER",pos=2)`
    `bmichild[,"GENDER"]`
    `# or`
    `rm(GENDER)`
    `GENDER`
    `# Note the existence of the following function:`
    `browseEnv()`
B- Creating a mini-package

- Objects in the package

7.1- `setwd(choose.dir())`
   # alternatively, under Linux:
   `library(tcltk)
   setwd(tk_choose.dir())`

7.2- Create the two functions and the data sets:
   
   ```r
   f <- function(x,y) x+y
   g <- function(x,y) x-y
   d <- data.frame(a=1,b=2)
   e <- rnorm(1000)
   ```

7.3- `package.skeleton(name="SmallRPkg",list=c("f","g","d","e"))`

7.4- Effective creation of the file of the package. You must modify the help files .Rd.

   ```r
   file.show(file.path(R.home("doc"),"KEYWORDS"))
   ```

7.5- Modify the file DESCRIPTION.

7.6- Read then delete the file Read-and-delete-me.

7.7- Checking (and possibly modification) of the PATH environment variable.

7.8- In a DOS command window, type the following instructions:

   ```r
   # Change to the folder containing your package:
   cd C:\Documents and Settings\johndoe\desktop
   R CMD check SmallRPkg
   R CMD INSTALL --build SmallRPkg
   ```

7.9- Install your package SmallRPkg.zip. For this, type for example:

   ```r
   help(package="SmallRPkg")
   help(d)
   ```
Solutions to Worksheet from Chapter 8

Matrix operations, optimization, integration

A- A first optimization problem

8.1- \( A <- \text{matrix(c(2,3,5,4),nrow=2,ncol=2)} \)
    \[ \text{myf <- function(x) \{} \]
    \[ \text{res <- det(A-x*diag(2))} \]
    \[ \text{return(res)} \]
    \[ \} \]

8.2- \[ \text{myf <- function(x) \{} \]
    \[ \text{n <- length(x)} \]
    \[ \text{res <- rep(NA,n)} \]
    \[ \text{for (i in 1:n) res[i] <- det(A-x[i]*diag(2))} \]
    \[ \text{return(res)} \]
    \[ \} \]

8.3- \[ \text{curve(myf,xlim=c(-10,10))} \]
    \[ \text{abline(h=0,v=0)} \]

Note that we can use the instruction `locator(2)$x` to “find” the two roots.

8.4- \[ \text{uniroot(myf,lower=-5,upper=0)$root} \]
    \[ \text{uniroot(myf,lower=0,upper=10)$root} \]

8.5- The polynomial can be written
    \[ P(x) = -7 - 6x + x^2. \]
    Its roots are obtained using:
    \[ \text{polyroot(c(-7,-6,1))} \]

8.6- \[ \text{eigen(A)$values} \]

B- A second optimization problem

8.1- To simplify things, we do not reproduce the figure at the correct scale.
    \[ \text{plot.new()} \]
    \[ \text{par(xpd=NA)} \]
    \[ \text{rect(0,0,1,1)} \]
    \[ \text{points(0,1,pch=16)} \]
    \[ \text{text(0,1,"A",adj=c(2,-0.1),col="blue")} \]
    \[ \text{points(1,1,pch=16)} \]
    \[ \text{text(1,1,"B",adj=c(-1,0),col="blue")} \]
8.2- We have $\cos(\alpha) = MQ/MB$ hence $MB = 5/\cos(\alpha)$ and $MA = MB$. $MH = BC - BQ$, $\tan(\alpha) = BQ/MQ = BQ/(AB/2)$ so $BQ = 5\tan(\alpha)$ and $MH = 6 - 5\tan(\alpha)$. Thus $g(\alpha) = 10/\cos(\alpha) + 6 - 5\tan(\alpha) = (10 - 5\sin(\alpha))/\cos(\alpha) + 6 = 5(2 - \sin(\alpha))/\cos(\alpha) + 6$.

8.3- $g <- function(\alpha){5*(2-sin(\alpha))/cos(\alpha)+6}$

8.4- optimize(g,lower=0,upper=pi/2,tol=0.000001)

8.5- $g'(\alpha) = 5(-\cos^2(\alpha) - (2 - \sin(\alpha))/(-\sin(\alpha))) / \cos^2(\alpha) = 5(-\cos^2(\alpha) + 2\sin(\alpha) - \sin^2(\alpha))/\cos^2(\alpha) = 5(2\sin(\alpha) - 1)/\cos^2(\alpha)$ since $\cos^2(\alpha) + \sin^2(\alpha) = 1$.

8.6- D(expression(5*2*(sin(\alpha)-1)/(cos(\alpha))^2),"\alpha")

8.7- gprime <- function(\alpha){5*(2*sin(\alpha)-1)/(cos(\alpha))^2}

8.8- uniroot(gprime,lower=0,upper=pi/2,tol=0.000001)$root

C- Standard normal table

8.1- phi <- function(x) {exp(-x^2/2)/sqrt(2*pi)}

8.2- quantiles <- seq(0,5.5,by=0.01)
    n <- length(quantiles)
    probs <- vector(mode="numeric",length=n)
    for (i in 1:n) probs[i] <- integrate(phi,lower=-Inf, upper=quantiles[i],rel.tol=0.00001)$value

8.3- all.equal(probs,pnorm(quantiles))

8.4- plot(c(rev(-quantiles),quantiles),c(rev(1-probs),probs),type="1")
D- Principal components analysis

8.1- url <- "http://www.biostatisticien.eu/springeR/climatewine.csv"
climatewine <- read.table(url,sep="\t",header=TRUE)
attach(climatewine)

8.2- X <- as.matrix(climatewine[,-c(1,6)])

8.3- g <- colMeans(X)
round(g,2)

8.4- Xdot <- scale(X,scale=FALSE)

8.5- n <- nrow(X)
inertia <- sum(Xdot^2)/n

8.6- inertiacontr <- rowSums(Xdot^2)/n/inertia
inertiacontr

8.7- onen <- as.matrix(rep(1,n))

8.8- g
(g <- t(X)^%tonen/n)

8.9- Xdot
(Xdot <- X-onen^%t(g))

8.10- (S <- t(Xdot)^%Xdot/n)
cov(X)*(n-1)/n

8.11- Doneovers <- diag(1/sqrt(diag(S)))

8.12- Z <- Xdot^%Doneovers

8.13- t(Z)^%Z/n
(R <- cor(X))

8.14- Lambda <- diag(eigen(R)$values)
W <- eigen(R,symmetric=TRUE)$vectors

8.15- theta <- seq(0,2*pi,.05)
x <- cos(theta)
y <- sin(theta)
plot(x,y,type="l")
abline(h=0,v=0)
\begin{verbatim}
A <- W %*% Lambda^(1/2)
text(A[,1:2],colnames(X))
arrows(rep(0,4),rep(0,4),A[,1],A[,2],length=0.1)

dimensions: 595.3x841.9

A <- W %*% Lambda^(1/2)
text(A[,1:2],colnames(X))
arrows(rep(0,4),rep(0,4),A[,1],A[,2],length=0.1)

8.16- p <- ncol(X)
cumsum(diag(Lambda))/p*100

The first two axes explain 87.6% of the total inertia.

8.17- CW <- Z %*% W

8.18- dev.new()
plot(CW[,c(1,2)],type="p",xlab="Axis 1",ylab="Axis 2")
text(CW[,c(1,2)],labels=YEAR)
abline(h=0,v=0)

8.19- plot(CW[,c(1,2)],type="n",xlab="Axis 1",ylab="Axis 2")
good <- CW[QUALITY==1,c(1,2)]
average <- CW[QUALITY==2,c(1,2)]
mediocre <- CW[QUALITY==3,c(1,2)]
text(good,labels=YEAR[QUALITY==1],col="red")
text(average,labels=YEAR[QUALITY==2],col="blue")
text(mediocre,labels=YEAR[QUALITY==3],col="green")
abline(h=0,v=0)
legend("topleft",c("good","average","mediocre"),fill=c("red","blue","green"))

8.20- QLT <- apply(sweep(CW^2,1,apply(CW^2,FUN=sum,1),FUN="/"))[1:2],FUN=sum,1)
round(QLT,2)

8.21- require(ade4)

8.22- rownames(X) <- climatewine[,1]
    res <- dudi.pca(X) # Enter 2 for the number of axes.
    scatter(res)
    s.class(res$li,as.factor(climatewine[,6]))
\end{verbatim}

---

Solutions to Worksheet from Chapter 9

Descriptive data studies

A- Thoughts on independence in descriptive statistics

snee <- read.table(url/header=TRUE)
9.2 - head(snee)
   tail(snee)
   dim(snee)
   str(snee)

There are 592 individuals and 3 qualitative variables.

9.3 - attach(snee)
   names(snee)
   class(hair)
   levels(hair)
   class(eyes)
   levels(eyes)
   class(gender)
   levels(gender)

9.4 - Study of the variable hair:

   table(hair) # Frequencies.
   round(table(hair)/length(hair)*100,2) # Frequencies in percentage.
   names(which.max(table(hair))) # Mode of the variable.
   barplot(sort(table(hair),TRUE),col=c("yellow2","tan4","black","tan1"))

   Study of the variable eyes:

   table(eyes) # Frequencies.
   round(table(eyes)/length(eyes)*100,2) # Frequencies in percentage.
   names(which.max(table(eyes))) # Mode of the variable.
   barplot(sort(table(eyes),TRUE),col=c("blue","brown","tan3","green"))

   Study of the variable gender:

   table(gender) # Frequencies.
   round(table(gender)/length(gender)*100,2) # Frequencies in percentage.
   names(which.max(table(gender))) # Mode of the variable.
   barplot(sort(table(gender),TRUE),col=c("pink","blue"),pareto=TRUE)

9.5 - eyeshair <- table(eyes,hair) # Contingency table.

9.6 - fhair <- margin.table(eyeshair,2)/592 # Column profiles.
   fhair

9.7 - # Number of individuals having blue eyes:
   nblue <- margin.table(eyeshair,1)[1]
   nblue

9.8 - round(fhair*nblue)

9.9 - marginX <- margin.table(eyeshair,1)
   tab.ind1 <- marginX%*%t(fhair)
   round(tab.ind1)
9.10- `feyes <- margin.table(eyeshair,1)/592` # Row profiles.

feyes

9.11- # Number of individuals having blond hair:
`nblond <- margin.table(eyeshair,2)[1]`
nblond

9.12- `round(feyes*nblond)`

9.13- `marginY <- margin.table(eyeshair,2)`
`tab.ind2 <- feyes%*%t(marginY)`
`round(tab.ind2)`

9.14- `all.equal(tab.ind1,tab.ind2)`

   The two tables are identical, which is reassuring since interest in the independence of the eyes and hair is equivalent to an interest in the independence of the hair and eyes.

9.15- `(eyeshair-tab.ind1)^2`

9.16- `tab.contr <- (eyeshair-tab.ind1)^2/tab.ind1`
tab.contr

9.17- `chi2 <- sum(tab.contr)`
`chi2`

   `Phi2 <- chi2/sum(eyeshair)`
   Phi2

   `C <- sqrt(chi2/(sum(eyeshair)+chi2))`
   C

   `V2 <- Phi2/(min(dim(eyeshair))-1)`
   V2

   All these indicators are not zero, so there is some form of dependence in this population (studied under the descriptive statistics framework).

9.18- # Conditionnal distributions of the variable hair
   # given that eyes = (blue, or brown or ...):
   `prop.table(eyeshair,1)`

   Rows are not identical. This confirms the dependency (from a descriptive statistics perspective) between the two variables.

   # Conditionnal distributions of the variable eyes
   # given that hair = (blond or ...):
   `prop.table(eyeshair,2)`

   Columns are not identical. This also confirms the dependency (from a descriptive statistics perspective) between the two variables.
9.19- `table(hair, gender)`
`plot(hair ~ gender)`
`plot(table(hair, gender))`

9.20- `table(eyes, gender)`
`plot(eyes ~ gender)`
`plot(table(eyes, gender))`

9.21- See worksheet in Chapter 2 to know how to import the table, then follow the steps above.

**B- Descriptive analysis of data set **NutriElderly

9.1- `require(gdata)`
`url <- "http://www.biostatisticien.eu/springerR/nutrition_elderly.xls"`
`nutrition <- read.xls(url, header=TRUE)`
`attach(nutrition)`

9.2- `names(which.max(table(situation)))`
`names(which.max(table(chocol)))`
`names(which.max(table(height)))`

9.3- `res <- hist(height, breaks=seq(140, 190, by=5), right=TRUE, plot=FALSE)`
`ind <- which.max(res$count)`
`modal.class <- paste(res$breaks[ind], res$breaks[ind+1], sep="-")`

The modal class is the class $[155; 160]$.

9.4- `median(chocol)`

Note that if the studied variable is considered as an ordinal variable, then the function `median()` of R does not work anymore:

`median(as.ordered(chocol))`

But we can propose a self made function to realize this operation:

```r
my.median <- function(x) {
  if (is.numeric(x)) return(median(x))
  if (is.ordered(x)) {
    N <- length(x)
    if (N%%2) return(sort(x)[(N+1)/2]) else {
      inf <- sort(x)[N/2]
      sup <- sort(x)[N/2+1]
      if (inf==sup) return(inf) else return(list(inf, sup))
    }
  }
  stop("Computation of the median not possible for this type.")
}
my.median(as.ordered(chocol))
```
9.5- `table(chocol)``table(raw_fruit)`

9.6- We can use the following self-made function:
```r
define <- function(tabx) names(which.max(cumsum(tabx)/sum(tabx)>0.5))
med <- define(table(chocol))
med <- define(table(raw_fruit))
```

9.7- ```r
quartile.on.freq <- function(tabx, quart) {
  # tabx is the table of frequencies.
  tab.freq.cum <- cumsum(tabx)/sum(tabx)
  index <- order(tab.freq.cum < quart)[1]
  f1 <- tab.freq.cum[index]
  f2 <- tab.freq.cum[index-1]
  x1 <- as.numeric(names(f1))
  x2 <- as.numeric(names(f2))
  quartile <- as.numeric(x1 + (x2-x1)*(quart-f1)/(f2-f1))
  return(quartile)
}
```
```r
  tab <- res$counts
  names(tab) <- res$breaks[-1]

  quartile.on.freq(tab, 0.25)
  quartile.on.freq(tab, 0.5)
  quartile.on.freq(tab, 0.75)
```

9.8- ```r
breaks <- res$breaks
plot(breaks, ecdf(height)(breaks), type="l", main=
  paste("Cumulated frequency polygon",
  "of variable height", sep="\n"), ylab="Frequencies",
  col="darkolivegreen", lwd=3)
abline(h=c(0.25, 0.5, 0.75))
locator(1)$x # Click on the searched intersection.
```

9.9- ```r
  mean(height)
  mean(weight)
  mean(age)
```

9.10- ```r
  table(tea)
  sum(c(0:6, 9, 10)*as.numeric(table(tea)))/sum(table(tea))
```

9.11- ```r
  sum(res$mids*res$counts)/sum(res$counts)
```

9.12- ```r
  diff(range(weight))
```

9.13- ```r
  boxplot(weight)
```
9.14- var.pop <- function(x) var(x)*(length(x)-1)/length(x)
    sd.pop <- function(x) sqrt(var.pop(x))
    sd.pop(height)

9.15- coeffvar.tab <- function(tabx) {
    val <- as.numeric(names(tabx))
    freq <- as.numeric(tabx)/sum(tabx)
    mean <- sum(val*freq)
    var <- sum(val^2*freq) - mean^2
    res <- sqrt(var)/mean
    return(res)
}
    coeffvar.tab(table(tea))

9.16- eta2 <- function(x,gp) {
    means <- tapply(x,gp,mean)
    frequencies <- tapply(x,gpe, length)
    varinter <- (sum(frequencies * (means - mean(x))^2))
    vartot <- (var(x) * (length(x) - 1))
    res <- varinter/vartot
    list(var.tot=vartot,var.inter=varinter,
         var.intra=vartot-varinter,eta2=res)
}
    res <- eta2(tea,gender)

Solutions to Worksheet from Chapter 10

Simulations

A- Study of the distribution \( f(x) = \frac{3}{2} \sqrt{x} \) on \([0, 1]\)

10.1- f <- function(x) (3/2)*sqrt(x)
    integrate(f,lower=0,upper=1)

10.2- Method of generic inversion:
    Finv <- function(x) x^((2/3))
    u <- runif(1000)
    x <- Finv(u)

10.3- mean(x)
    var(x)
10.4- Theoretical values are $E(X) = 3/5$ and $\text{Var}(X) = 12/175$.

10.5- The cumulative distribution function is $F(x) = x^{2/3}$. The theoretical probabilities of the various classes are: $0.3^{3/2} = 0.1643168$, $0.5^{3/2} - 0.3^{3/2} = 0.1892366$, $0.7^{3/2} - 0.5^{3/2} = 0.2321086$, $0.85^{3/2} - 0.7^{3/2} = 0.1979993$ and $1 - 0.85^{3/2} = 0.2163387$. We can evaluate them numerically:

```r
class <- c(0.3, 0.5, 0.7, 0.85)
prob <- function(x) {integrate(f, lower=0, upper=x)$value}
dist <- c(0, apply(as.matrix(class), MARGIN=1, FUN=prob), 1)
(theoretical.prob <- diff(dist))
```

The empirical probabilities can be computed using the following code:

```r
count <- function(x, vect.y) sum(vect.y < x) / length(vect.y)
empirical.dist <- c(0, apply(as.matrix(class), MARGIN=1, FUN=count, x), 1)
(empirical.prob <- diff(empirical.dist))
```

or the following code:

```r
c(mean(0 <= x & x <= 0.3), mean(0.3 < x & x <= 0.5), mean(0.5 < x & x <= 0.7),
mean(0.7 < x & x <= 0.85), mean(0.85 < x & x <= 1))
```

B- Study of the generalized Pareto distribution

10.1- `rGP <- function(n, mu, sigma, xi) mu + sigma^((runif(n))^(-xi) - 1)/xi`

10.2- n <- 1000
simu <- rGP(n, 0, 1, 0.25)

10.3- mean(simu)
var(simu)

10.4- mu <- 0
sigma <- 1
xi <- 0.25
(theo.mu <- mu + sigma/(1-xi))
(theo.var <- (sigma^2)/(((1-xi)^2) * (1-2*xi)))

10.5- n <- 10000
simu.new <- rGP(n, 0, 1, 0.25)
mean(simu.new)
var(simu.new)

10.6- hist(simu.new, breaks=500, xlim=c(0,10), prob=TRUE, col="red")

10.7- `dens.pareto <- function(x, mu, sigma, xi) {
    (1/sigma)^(((1+(xi*(x-mu))/sigma)^(-1))/xi-1)
}
curve(dens.pareto(x, mu, sigma, xi), add=TRUE, col="blue")`
C- Uniform distribution on a square

10.1- \( n \leftarrow 1000 \)
\( \text{simu} \leftarrow \text{data.frame(X1=runif(n),X2=runif(n))} \)

10.2- The distance of \((X_1, X_2)\) to the nearest edge is given by \(D = \min(X_1, X_2, 1 - X_1, 1 - X_2)\) (make a drawing to be convinced).
\( \text{simu.d} \leftarrow \text{cbind(simu,1-simu)} \)
\( D \leftarrow \text{apply(simu.d,MARGIN=1,FUN=min)} \)
\( \text{mean}(D<0.25) \)

10.3- \( \text{dist.sum} \leftarrow \text{function(coord)} \{ \)
\( d \leftarrow \text{sqrt(d)} \)
\( \text{D.sum} \leftarrow \text{apply(simu.d,MARGIN=1,FUN=dist.sum)} \)
\( \text{mean}(D\.sum<0.25) \)

10.4- \( \text{mean}(D) \)
\( \text{var}(D) \)
\( \text{hist}(D,\text{prob=}TRUE) \)
\( \text{curve}(-8*x+4,\text{add=}TRUE) \)
\( \# \text{ Density on } [0,0.5] : f(x)=-8x+4 \)

D- Towards modelling

10.1- \( X \leftarrow \text{function()} \text{ifelse(rbinom(1,1,0.5),"HEADS","TAILS")} \)
\( X() \)

10.2- \( \text{throw.of.a.die} \leftarrow \text{function()} \text{sample(1:6,1)} \)
\( \text{throw.of.a.die}() \)

10.3- \( \text{yams} \leftarrow \text{function()} \text{sample(1:6,\text{size=}5,\text{replace=}TRUE)} \)

10.4- \( n \leftarrow 1000000 \)
\( \text{result} \leftarrow \text{replicate(n,yams(),\text{TRUE})} \)
\( \text{test} \leftarrow \text{function(res) ifelse(length(unique(res))> 1,0,1)} \)
\( \text{prop} \leftarrow \text{mean(apply(result,MARGIN=2,FUN=test))} \)

E- Box-Muller theorem
10.1- n <- 1000
    u1 <- runif(n)
    u2 <- runif(n)
    z1 <- sqrt(-2*log(u1))*cos(2*pi*u2)
    z2 <- sqrt(-2*log(u1))*sin(2*pi*u2)

10.2- Non parametric estimation of the density:
    require(MASS)
    ngrid <- 40
    denobj <- kde2d(z1,z2,n=ngrid)
    den.z <- denobj$z

10.3- Surface of the density of the bivariate normal:
    require(rgl)
    xgrid <- denobj$x
    ygrid <- denobj$y
    bi.z <- dnorm(xgrid)*dnorm(ygrid)

    New window:
    open3d()
    bg3d(color="#887777")
    light3d()

    Representing simulated data:
    spheres3d(z1,z2,rep(0,n),radius=0.1,color="#CCCCFF")

    Representing the non parametric estimated density:
    surface3d(xgrid,ygrid,den.z*20,color="#FF2222",alpha=0.5)

    Representing the standard bivariate normal:
    surface3d(xgrid,ygrid,bi.z*20,color="#CCCCFF",front="lines")
A- Study of confidence intervals

11.1- n <- 20
M <- 50000
ech <- rnorm(n,mean=-1.2,sd=sqrt(2)) # Only a sample.
simu <- replicate(M,rnorm(n,mean=-1.2,sd=sqrt(2)),simplify=TRUE)

11.2- inter.mu <- function(x) t.test(x,conf.level=0.9)$conf.int
res <- t(apply(simu,MARGIN=2,FUN=inter.mu))

11.3- prop <- mean((res[,1] < -1.2) & (-1.2 < res[,2]))

Around 90% of the intervals contain the value -1.2.

11.4- n <- 100
M <- 50000
simu <- replicate(M,rchisq(n,df=1),simplify=TRUE)
res.chi2 <- t(apply(simu,MARGIN=2,FUN=inter.mu))
prop <- mean((res.chi2[,1] < 1) & (1 < res.chi2[,2]))

The (empirical) level of confidence of the interval is not equal to 90%. This is due to the small sample size (n = 10), which is not sufficient to use the central limit theorem.

11.5- n <- 10
M <- 50000
simu <- replicate(M,rchisq(n,df=1),simplify=TRUE)
res.chi2 <- t(apply(simu,MARGIN=2,FUN=inter.mu))
prop <- mean((res.chi2[,1] < 1) & (1 < res.chi2[,2]))

11.6- n <- 20
ech.20 <- rnorm(n,mean=-1.2,sd=sqrt(2))
inter.mu <- function(x) t.test(x,conf.level=0.95)$conf.int
inter.mu(ech.20)

11.7- ech.50 <- rnorm(50,mean=-1.2,sd=sqrt(2))
inter.mu(ech.50)

ech.100 <- rnorm(100,mean=-1.2,sd=sqrt(2))
inter.mu(ech.100)

ech.1000 <- rnorm(1000,mean=-1.2,sd=sqrt(2))
inter.mu(ech.1000)

ech.10000 <- rnorm(10000,mean=-1.2,sd=sqrt(2))
inter.mu(ech.10000)
ech.100000 <- rnorm(100000, mean=-1.2, sd=sqrt(2))
inter.mu(ech.100000)

The confidence interval gets narrower around the true value of $\mu$.

11.8-

$$
tt.20 <- c(t.test(ech.20)$st, t.test(ech.20)$p.val)
tt.50 <- c(t.test(ech.50)$st, t.test(ech.50)$p.val)
tt.100 <- c(t.test(ech.100)$st, t.test(ech.100)$p.val)
tt.1000 <- c(t.test(ech.1000)$st, t.test(ech.1000)$p.val)
tt.10000 <- c(t.test(ech.10000)$st, t.test(ech.10000)$p.val)
tt.100000 <- c(t.test(ech.100000)$st, t.test(ech.100000)$p.val)
output <- rbind(tt.20, tt.50, tt.100, tt.1000, tt.10000, tt.100000)
colnames(output) <- c("tobs", "pvalue")
output

As $n$ increases, $t_{obs}$ increases and the $p$-value gets smaller. It becomes more and more difficult to "show" that $\mu$ is different from 0.

11.9-

inter.mu(ech.100000)
t.test(ech.100000, mu=-1.1)$p.val

tt.50

The $p$-value is smaller here although $-1.1$ is nearer from the true $\mu$ ($= -1.2$) than the reference value 0 used at the previous question. On the other side, the confidence interval does not deceive. We see the interest of confidence intervals as compared to only giving the $p$-value!

- Study of confidence intervals from bootstrap

11.1-

n <- 20
M <- 500
ech <- rexp(n, rate=1/10) # only one sample
simu.exp <- replicate(M, rexp(n, rate=1/10), simplify=TRUE)

11.2-

For one sample:

require(boot)
mean <- function(x, indices) mean(x[indices])
mean.boot <- boot(simu.exp[,3], mean, R=999, type="i", sim="ordinary")
boot.ci(mean.boot, conf=0.9, type="perc")$percent[4:5]

For $M$ samples:

inter.boot.mean <- function(y) {
  mean <- boot(y, mean, R=999, type="i", sim="ordinary")
  boot.ci(mean, conf=0.9, type="perc")$percent[4:5]
}
res <- rbind(simu.exp, MARGIN=2, FUN=inter.boot.mean)
11.3- prop.boot <- mean((res[,1] < 10) & (res[,2] > 10))

11.4- res.ttest <- t(apply(simu.exp,MARGIN=2,FUN=inter.mu))
    prop.ttest <- mean((res.ttest[,1] < 10) & (res.ttest[,2] > 10))

B- Study of risks in hypothesis testing

- Study of risk of the first kind

11.1- n <- 20
    M <- 500
    ech <- rnorm(n,mean=4,sd=sqrt(1.2)) # Only one sample.
    simu <- replicate(M,rnorm(n,mean=4,sd=sqrt(1.2)),simplify=TRUE)

11.2- ttest <- function(x) t.test(x,mu=4)$p.value
    res <- apply(simu,MARGIN=2,FUN=ttest)

11.3- (count <- sum(res < 0.05))
     count hypotheses are rejected; we expect to reject 25 null hypotheses.

11.4- M <- 5000
    simu <- replicate(M,rnorm(n,mean=4,sd=sqrt(1.2)),simplify=TRUE)
    res <- apply(simu,MARGIN=2,FUN=ttest)
    proportion <- mean(res < 0.05)

11.5- n <- 100
    M <- 5000
    simu <- replicate(M,rchisq(n,df=1),simplify=TRUE)
    ttest <- function(x) t.test(x,mu=1)$p.value
    res.chi2 <- t(apply(simu,MARGIN=2,FUN=ttest))
    proportion <- mean(res.chi2 < 0.05)

11.6- n <- 10
    M <- 5000
    simu <- replicate(M,rchisq(n,df=1),simplify=TRUE)
    ttest <- function(x) t.test(x,mu=1)$p.value
    res.chi2 <- t(apply(simu,MARGIN=2,FUN=ttest))
    proportion <- mean(res.chi2 < 0.05)

The risk of the first kind of the test is greater than 5% because the Student test is not valid here due to a small sample size.

11.7- IC.p <- t.test((res.chi2<0.05)*1)$conf
     IC.p
# or also:
binom.test(sum(res.chi2<0.05),length(res.chi2))$conf

- **Study of power**

11.1- n <- 20  
   M <- 500  
   simu <- replicate(M,rnorm(n,mean=5,sd=sqrt(1.2)),simplify=TRUE)

11.2- ttest <- function(x) t.test(x,mu=4)$p.value  
   res <- apply(simu,MARGIN=2,FUN=ttest)

11.3- count <- sum(res < 0.05)  
   power <- mean(res < 0.05)

11.4- n <- 100  
   M <- 500  
   simu <- replicate(M,rnorm(n,mean=5,sd=sqrt(1.2)),simplify=TRUE)  
   res <- apply(simu,MARGIN=2,FUN=ttest)  
   (power <- mean(res < 0.05))

   The power is 100%. It has increased with the sample size.

11.5- n <- 100  
   M <- 500  
   simu <- replicate(M,rchisq(n,df=2),simplify=TRUE)  
   ttest <- function(x) t.test(x,mu=1)$p.value  
   res.chi2 <- apply(simu,MARGIN=2,FUN=ttest)  
   proportion <- mean(res.chi2 < 0.05)

11.6- n <- 10  
   M <- 500  
   simu <- replicate(M,rchisq(n,df=2),simplify=TRUE)  
   ttest <- function(x) t.test(x,mu=1)$p.value  
   res.chi2 <- t(apply(simu,MARGIN=2,FUN=ttest))  
   proportion <- mean(res.chi2 < 0.05)

   The power of the test is low due to a small sample size \( n = 10 \). We do not have enough information to show that the mean is different from 1.

**C- A few practical examples**

- **Cow study**
11.1- just.after.milking <- c(12000,13000,21500,17000,15000,22000,11000,21000)
after.milking.24h <- c(11000,20000,31000,28000,26000,30000,16000,29000)
t.test(just.after.milking,after.milking.24h,paired=TRUE,alt="less")

11.2- # Test of signs:
dif <- just.after.milking - after.milking.24h
sminus <- sum(dif<0)
splus <- sum(dif>0)
binom.test(min(splus,sminus),splus+sminus,alt="less")

11.3- # Mann-Whitney's test:
wilcox.test(just.after.milking,after.milking.24h,paired=TRUE,
exact=FALSE,alt="less")

- East German athletes

11.1- hormons <- c(3.22,3.07,3.17,2.91,3.4,3.58,3.23,3.11,3.62)
t.test(hormons,mu=3.1,alt="greater")

11.2- The average amount of androgens for athletes in East Germany is significantly higher than the average reference 3.1. They are doped.

- Drinking and driving

before <- c(57,54,62,64,71,65,70,75,68,77,74,80,83)
after <- c(55,60,68,69,70,73,74,74,75,76,78,81,90)
t.test(before,after,paired=TRUE)

- Speed of light

11.1- speed <- c(850,740,900,1070,930,850,950,980,980,880,1000,980,930,1050,960,810,1000,1000,960,960)
speed <- speed + 299000
hist(speed)
There is a very visible absolute mode.

11.2- shapiro.test(speed)

11.3- t.test(speed,mu=299990)

11.4- mean(speed)
• Cholesterol levels

groupA <- c(46.3, 42.5, 43, 43.9, 42, 41.5, 41.6, 44.4, 40.7)
groupB <- c(47.1, 44.5, 45.8, 49, 44.6, 43.7, 44.5, 47.4)
t.test(groupA, groupB, alt="less")

We can conclude that the treatment is efficient at significance level $\alpha = 5\%$.

• Treatment-death independence

x <- matrix(c(0, 9, 8, 3), ncol=2, byrow=TRUE)
# Table of theoretical frequencies:
chisq.test(x)$exp # Some values are < 5.
chisq.test(x) # Yates chi-2.
fisher.test(x) # Fisher's exact test.

Mortality depends on the treatment.

• Number of patients in the emergency ward

files <- c(1500, 1600, 1450)
cases <- c(675, 720, 610)
chisq.test(cases/files)

In view of the results, we can not conclude that the proportion of emergencies is different depending on the month.

Solutions to Worksheet from Chapter 12

A- Study of simple linear regression

• Study of synthetic data

12.1- n <- 50
b0 <- 1
b1 <- 2
sigma <- 0.1
t <- 5
terror <- rnorm(n, sd=sigma)
x <- runif(n,min=0,max=t)
y <- b0+b1*x+error

12.2- plot(y~x)

12.3- model <- lm(y~x)
coefficients(model)
  sd(residuals(model)) * sqrt((n-1)/(n-2))
  # or also:
  summary(model)[6]

12.4- plot(model,1:2)
plot(model$fitted~y)

12.5- precision.parameter.b1 <- function(n,sigma) {
  error <- rnorm(n,sd=sigma)
  x <- runif(n,min=0,max=t)
  y <- b0 + b1*x + error
  model <- lm(y~x)
  summary(model)$coef[2,2]
}

size <- seq(50,1000,by=50)
sd.b1 <- vector("numeric",20)
for (i in 1:20) {
  sd.b1[i] <- precision.parameter.b1(size[i],0.1)
}

We can see on the graph below, the precision of the estimate of b1 according to n for a noise standard deviation equal to 0.1:

plot(sd.b1~size,xlab="n",
  ylab="Estimation of standard deviation of the estimator of b1",
  main="Precision of the estimation of b1 as a function of n")

On the chart below, we can see the accuracy of the estimate of b1 according to sigma for n equal to 100:

sd <- seq(0.1,10,by=0.1)
sd.b1 <- vector("numeric",100)
for (i in 1:100) {
  sd.b1[i] <- precision.parameter.b1(n=100,sd[i])
}

title <- "Precision of the estimation of b1 as a function \n of the standard deviation of the noise"
plot(sd.b1~sd,xlab=expression(sigma),ylab=
  "estimation of the standard deviation of the estimator of b1",
  main=title)
• Study of intima-media

   require(gdata)
   intima.media <- read.xls(url,header=TRUE)
   attach(intima.media)

12.2- plot(measure ~ AGE)
   Increasing trend of the measure of the thickness of the intima-media as a function of AGE.

12.3- # Calculating the correlation coefficient between the two variables:
   cor(measure, AGE)
   # Test the significance of the coefficient of correlation:
   cor.test(measure, AGE)

12.4- model <- lm(measure ~ AGE, data=data.frame(measure, AGE))
   summary(model)
   abline(model, col="blue")

12.5- hist(residuals(model), main="Histogram")
   plot(model, 1:6)

12.6- age0 <- 33
   predict(model, data.frame(AGE=age0), interval="prediction")

12.7- predict(model, data.frame(AGE=age0), interval="confidence")

12.8- model2 <- lm(measure ~ I(AGE^2))
   summary(model2)
   The $R^2$ increased (a little bit).

B- Study of multiple linear regression

• Study of intima-media

   We notice (tobacco[is.na(packyear)] and packyear[tobacco==0]) that the variable packyear (giving the number of pack of cigarettes per year) contains missing values NA each time the variable tobacco takes the value 0 (meaning a non-smoker). It is thus natural to replace missing data of variable packyear with zeroes:
   intima.media$packyear[is.na(packyear)] <- 0

   Creation of the variable BMI:
BMI <- intima.media$weight/((intima.media$height/100)^2)
attach(intima.media)
my.data <- data.frame(AGE,SPORT,alcohol,packyear,BMI,measure)

12.1- pairs(my.data)

Some scatter plots have a linear trend, which can lead to collinearity.

12.2- model.age <- lm(measure~AGE,data=my.data)
summary(model.age)
model.sport <- lm(measure~SPORT,data=my.data)
summary(model.sport) ### p-value > 0.25
model.alcohol <- lm(measure~factor(alcohol),data=my.data)
summary(model.alcohol)
model.packyear <- lm(measure~packyear,data=my.data)
summary(model.packyear)
model.BMI <- lm(measure~BMI,data=my.data)
summary(model.BMI)

12.3- model.age.inter <- lm(measure~AGE*packyear)
# Non-significant interaction at 0.25 level:
summary(model.age.inter)

model.alcohol.without.inter <-
   lm(measure~factor(alcohol)+packyear,data=my.data)
model.alcohol.inter <-
   lm(measure~factor(alcohol)*packyear,data=my.data)
summary(model.alcohol.inter)
anova(model.alcohol.without.inter,model.alcohol.inter)

model.BMI.inter <- lm(measure~BMI*packyear,data=my.data)
# Non-significant interaction at level 0.25:
summary(model.BMI.inter)

12.4- model.inter <-
   lm(measure~AGE+factor(alcohol)*packyear+BMI,data=my.data)
summary(model.inter)

12.5- model.without.inter <- lm(measure~AGE+factor(alcohol)+packyear+BMI,data=my.data)
# The interaction term is not significant anymore:
anova(model.inter,model.without.inter)
summary(model.without.inter)

12.6- modele.without.alcohol <- lm(measure~AGE+packyear+BMI,data=my.data)
anova(modele.without.alcohol,model.without.inter)

The variable alcohol does not bring any information.

summary(model.without.alcohol)
12.7- In the final model, the measurement of intima-media is explained by the variables AGE and BMI, with an adjustment on the variable packyear. Whatever the number of packs of cigarettes smoked each year, the measurement of intima-media increases with age and BMI.

• Study of unemployment rates

    load("unemployment.RData")
    names(unemployment)
    attach(unemployment)

    model.txpib <- lm(unemp~gdprate,data=unemployment)
    summary(model.gdprate)
    plot(unemp~gdprate)
    abline(model.gdprate)

    hist(residuals(model.gdprate))
    plot(model.gdprate,1:2)

12.2- cor(unemp[,2:7])

12.3- pairs(unemp[,2:7])

12.4- Most explicative variables: taxb, govspend, gdprate. Colinear variables: govspend and taxb, as well as govspend and gdprate, and finally taxb and gdprate.

12.5- full.model <- lm(unemp~gdprate+govspend+taxb+salav+infl,data=unemployment)
    summary(full.model)

12.6- require(car)
    vif(full.model)

12.7- drop1(lm(unemp~gdprate+govspend+taxb+salav+infl,data=unemployment),test="F")
    # We remove variable infl.
    drop1(lm(unemp~gdprate+govspend+taxb+salav,data=unemployment),test="F")
    # We remove variable txpib.
    drop1(lm(unemp~govspend+taxb+salav,data=unemployment),test="F")
    # We remove variable pfisc.
    drop1(lm(unemp~govspend+salav,data=unemployment),test="F")

12.8- # Final model:
    final.model <- lm(unemp~govspend+salav,data=unemployment)
    summary(final.model)
12.9- govspend93 <- unemployment$govspend[unemployment$year==1993]
salav93 <- unemployment$salav[unemployment$year==1993]
predict(final.model,data.frame(govspend=govspend93,salav=salav93),
   interval="prediction")

12.10- The observed value of unemployment in 1993 was 11.2 and this value is
contained in the prediction interval.

C- Study of polynomial regression

- Study of synthetic data

12.1- n <- 100
   x <- runif(n,min=-2,max=2)
   eps <- rnorm(n)
   y <- x+2*(x^2)+3.5*(x^3)-2.3*(x^4)+eps

12.2- plot(y˜x)
   curve(x+2*x^2+3.5*x^3-2.3*x^4,add=TRUE)

12.3- simple.model <- lm(y˜x)
   summary(simple.model)
   hist(residuals(simple.model))
   plot(simple.model,1:6)

12.4- poly.model <- lm(y˜1+poly(x,4,raw=TRUE))
   summary(poly.model)
   coef <- coef(poly.model)
   plot(y˜x)
   curve(coef[1]*x+coef[2]*(x^2)+coef[3]*x^3+coef[4]*x^4,add=TRUE)

- Fitting a scatter plot with a polynomial

12.1- Download the file http://biostatisticien.eu/springeR/fitpoly.RData
   in your current directory.
   load("fitpoly.RData")
   attach(fitpoly)

12.2- plot(Y˜X)

12.3- lin.model <- lm(Y˜X)
   summary(lin.model)
   abline(lin.model)
12.4- poly.model <- lm(Y˜poly(X,3,raw=TRUE),data=fitpoly)
   summary(poly.model)

12.5- coef <- coef(poly.model)
   curve(coef[1]+coef[2]*x+coef[3]*x^2+coef[4]*x^3,add=TRUE)
   x <- seq(-3.5,3.5,length=50)
   pred.int <- predict(poly.model,data.frame(X=x),
                       interval="prediction")[,c("lwr","upr")]
   conf.int <- predict(poly.model,data.frame(X=x),
                       interval="confidence")[,c("lwr","upr")]
   matlines(x,cbind(conf.int,pred.int),lty=c(2,2,3,3),
            col=c("red","red","blue","blue"),lwd=c(2,2,1,1))
   legend("bottomright",lty=c(2,3),lwd=c(2,1),
          c("confidence","prediction"),col=c("red","blue"))

Solutions to Worksheet from Chapter 13

A- Study of one-way ANOVA

- Study of noise levels

13.1- noise <- gl(4,6,24)
   grade <- c(62,60,63,59,63,59,56,62,60,61,63,64,63,67,
              71,64,65,66,68,66,71,67,68,68)

13.2- grade_ik = µ + α_i + ε_ik where the ε_ik’s are i.i.d. random variables following a
      N(0,σ^2) distribution.

13.3- model <- aov(grade~noise)
   summary(model)

13.4- pairwise.t.test(grade,noise,p.adjust="bonf")
      TukeyHSD(model)

- Study of intima-media

      require(gdata)
      intima.media <- read.xls(url,header=TRUE)
      attach(intima.media)
13.2- plot(measure~factor(alcohol))

13.3- intima.model <- aov(measure~factor(alcohol))
    summary(intima.model)

    There exists a difference in the measure of thickness of intima-media depending on alcohol consumption (p-value<0.05).

13.4- plot(intima.model)
    # Homoscedasticity :
    require(car)
    leveneTest(measure,factor(alcohol))

• Study of physical activity

    load("sports.RData")
    attach(sports)

    Factor time of practicing sport (7 levels). score_{ik} = \mu + \alpha_i + \epsilon_{ik} where the \epsilon_{ik}`s are i.i.d. random variables following a \text{N}(0,\sigma^2) distribution.

13.2- sport.model <- aov(score~time)
    summary(sport.model)

13.3- cmat <- rbind(" : not athletic versus somewhat athletic"=c(1,1,-1,-1,0,0,0),
    " : very athletic versus not athletic"=c(3,3,0,0,-2,-2,-2))

13.4- require(gmodels)
    fit.contrast(sport.model,time,cmat)

B- Study of two-way ANOVA

• Study of batteries

13.1- Factor temperature with 3 levels: 15, 70 and 125 degrees. Factor type with 3 levels: I, II and III. Dependent variable: lifetime.
13.2- Y_{ijk} = \mu + \mu_j + \epsilon_{ijk} where the \epsilon_{ijk}`s are i.i.d. random variables following a \text{N}(0,\sigma^2) distribution.
13.3- lifetime <- c(130,155,74,180,34,40,80,75,20,70,82,58,150,188,159, 126,136,122,106,115,25,70,58,45,138,110,168,160,174, 120,150,139,96,104,82,60)
    temperature <- as.factor(rep(rep(1:3,each=4,3)))
levels(temperature) <- c("15°C", "70°C","125°C")
type.battery <- as.factor(rep(1:3,each=12))
levels(type.battery) <- c("type I","type II","type III")
battery <- data.frame(lifetime=lifetime,temperature=temperature,
  type.battery=type.battery)
interaction.plot(temperature,type.battery,lifetime)
interaction.plot(type.battery,temperature,lifetime)

13.4- summary(lm(lifetime~temperature*type.battery))
13.5- anova(lm(lifetime~temperature*type.battery))

Significant interaction: be careful about the interpretation of parameters and
tests of fixed effects, we must look at the conditional effects.

13.6- For example, test of the temperature effect for batteries of type I
model <- summary(aov(lifetime~temperature*type.battery))
lifetime.battery1 <- summary(aov(lifetime~temperature,
  subset=type.battery=="type I"))
lifetime.battery1
F.lifetime.battery1 <- lifetime.battery1[[1]]$Mean[1]/model[[1]]$Mean[4]
pvalue <- 1-pf(F.lifetime.battery1,df1=2,df2=27)

• Milk yield

13.1- Factor food with 4 levels: Straw, Hay, Grass, Silage. Factor dose with 2 levels
  : Low and High. Dependent variable: yield. $Y_{ijk} = \mu + \mu_i j + \epsilon_{ijk}$ where the
  $\epsilon_{ijk}$’s are i.i.d. random variables following a $N(0, \sigma^2)$ distribution.
13.2- yield <- c(8,11,11,10,7,12,13,14,11,10,12,12,13,14,17,
   13,17,14,13,8,9,8,10,9,10,7,10,12,11,11,9,11,
   11,12,13,12,11,15,14)
food <- as.factor(rep(rep(1:4,each=5,2)))
levels(food) <- c("Straw","Hay","Grass","Silage")
dose <- as.factor(rep(1:2,each=20))
levels(dose) <- c("Low", "High")
milk <- data.frame(yield=yield,food=food,dose=dose)
interaction.plot(food,dose,yield)
interaction.plot(dose,food,yield)

13.3- summary(lm(yield~dose*food))
13.4- anova(lm(yield~dose*food))

Non significant interaction: We will prefer a simpler model.
13.5- anova(lm(yield~dose+food))
• Intima-media study

    intima.media <- read.xls(url,header=TRUE)
    attach(intima.media)

13.2- Two way ANOVA model with an interaction term.
13.3- tobacco <- factor(tobacco)
      alcohol <- factor(alcohol)
      interaction.plot(tobacco,alcohol,measure)
      interaction.plot(alcohol,tobacco,measure)

13.4- require(car)
      intima.model <- Anova(lm(measure~alcohol*tobacco),type="III")
      intima.model
      # non-significant interaction:
      additive.intima.model <- Anova(lm(measure~alcohol+tobacco),type="III")
      # alcohol: p-value=0.09  Tobacco: p-value=0.16
